

ExGauge

The eXGauge / eXLayers library provides graphics capabilities to visually display and edit the amount, level, or contents of something. The view can show one or more layers, where each layer can display one or more transparent pictures, HTML captions which can be clipped, moved, rotated or combination of them, by dragging the mouse, rolling the mouse wheel, or using the keyboard. Using the eXGauge / eXLayers library you can easily simulate any gauges, thermometers, meters, clocks, buttons, sliders, scales, knobs, dials, switches, progress, status, indicators, LEDs, and so on. As usual, there are no dependencies to MFC, VB, VCL, or anything else.

Features include:

- Multiple Layers Support
- Ability to display the control's itself (no form, transparent form, no background) as an individual or child widget
- Any layer can display multiple graphics, images, HTML captions
- Ability to specify visible, selectable objects on any layer
- Any layer can be clipped, moved, rotated, or combination of any of these
- Clipping support include intersection of any of rectangle, round rectangle, ellipse, pie, picture mask, polygon, and so on
- Visibility / Transparency support
- Brightness, Contrast, Grayscale support
- Drag, Mouse-Wheel, Keyboard Support
- Mouse In, Mouse Out, Smooth Change Support
- High-Quality Rotation Support
- ToolTip support
- Debug Mode support, allows you to display debugging information
- Expression Support, for any angle, offset or clip's value

Ž ExGauge is a trademark of Exontrol. All Rights Reserved.

How to get support?

To keep your business applications running, you need support you can count on.

Here are few hints what to do when you're stuck on your programming:

- Check out the samples - they are here to provide some quick info on how things should be done
- Check out the how-to questions using the [eXHelper](#) tool
- Check out the help - includes documentation for each method, property or event
- Check out if you have the latest version, and if you don't have it send an update request [here](#).
- Submit your problem(question) [here](#).

Don't forget that you can contact our development team if you have ideas or requests for new components, by sending us an e-mail at support@exontrol.com (please include the name of the product in the subject, ex: exgrid) . We're sure our team of developers will try to find a way to make you happy - and us too, since we helped.

Regards,
Exontrol Development Team

<https://www.exontrol.com>

constants AnchorEnum

The AnchorEnum type specifies how the object is anchored. The [Caption\(exLayerCaptionAnchor\)](#) / [ExtraCaption\(...,exLayerCaptionAnchor\)](#) / [Foreground.Caption\(exLayerCaptionAnchor\)](#) / [Foreground.ExtraCaption\(,exLayerCaptionAnchor\)](#) property specifies how the caption is anchored. The AnchorEnum type supports the following values:

Name	Value	Description
exAnchorDock	0	The object is anchored to the host's client area.
exAnchorTop	1	The object is anchored to the top side of its host.
exAnchorBottom	2	The object is anchored to the bottom side of its host.
exAnchorLeft	4	The object is anchored to the left side of its host.
exAnchorRight	8	The object is anchored to the right side of its host.

constants AppearanceEnum

The AppearanceEnum type specifies how the control's border are shown. The [Appearance](#) property specifies the control's border. The Appearance property supports the following values:

Name	Value	Description
None2	0	No border
Flat	1	Flat border
Sunken	2	Sunken border
Raised	3	Raised border
Etched	4	Etched border
Bump	5	Bump border

constants BackgroundPartEnum

The BackgroundPartEnum type indicates parts in the control. Use the [Background](#) property to specify a background color or a visual appearance for specific parts in the control. A Color expression that indicates the background color for a specified part. The last 7 bits in the high significant byte of the color to indicates the identifier of the skin being used. Use the [Add](#) method to add new skins to the control. If you need to remove the skin appearance from a part of the control you need to reset the last 7 bits in the high significant byte of the color being applied to the background's part.

Name	Value	Description
exToolTipAppearance	64	Specifies the visual appearance of the borders of the tooltips. Use the ToolTipPopDelay property specifies the period in ms of time the ToolTip remains visible if the mouse pointer is stationary within a control. Use the ToolTip / ToolTipTitle property to specify the layer's tooltip. Use the ToolTipWidth property to specify the width of the tooltip window. The ToolTipDelay property specifies the time in ms that passes before the ToolTip appears. Use the ShowToolTip method to display a custom tooltip.
exToolTipBackColor	65	Specifies the tooltip's background color.
exToolTipForeColor	66	Specifies the tooltip's foreground color.

constants ColorAdjustmentChannelEnum

The ColorAdjustmentChannelEnum type specifies the color channel to be updated by the [Brightness](#) / [Contrast](#) properties. These properties can be used to change the percent of specified color to be applied on the layer. The ColorAdjustmentChannelEnum defines the following values:

Name	Value	Description
exAllChannels	0	The value is applied to all channels (red, green and blue).
exRedChannel	1	The value is applied to the red channel only
exGreenChannel	2	The value is applied to the green channel only
exBlueChannel	3	The value is applied to the blue channel only

constants DebugLayerDragEnum

A DebugLayerDragEnum type the holds what information the debugging the drag operation should display. The [Debug](#) property specifies debugging information to be shown while dragging the layers.

The following information shows all debug information while dragging the layer:

The DebugLayerDragEnum type supports the following flags:

Name	Value	Description
exDebugLayerDragNothing	0	No debug information is displayed.
exDebugLayerDragHighlight	256	Specifies that layers should be shown with a semi-transparent color, so the debugging information is more clear.
exDebugLayerDragClick	1	Shows the point where the drag operation begins. The X property indicates the x-position of the cursor, when the drag operation starts and the Y property indicates the y-position of the cursor, when the drag operation starts.
		Shows the current dragging point. The CurrentX property indicates the current x-position of the

exDebugLayerDragCurrent	2	cursor, while dragging the layer and the CurrentY property indicates the current y-position of the cursor, while dragging the layer.
exDebugLayerDragDeltaX	4	Shows the horizontal offset. The DeltaX property returns the offset on the x-coordinate of the the current drag operation, equivalent with the value of CurrentX - X.
exDebugLayerDragDeltaY	8	Shows the vertical offset. The DeltaY property returns the offset on the y-coordinate of the the current drag operation, equivalent with the value of CurrentY - Y.
exDebugLayerDragDelta	16	Shows the distance between clicking and current point. The Delta property, returns the distance between clicking and current points.
exDebugLayerDragMove	287	Shortcut flag for move operation by dragging. It combines exDebugLayerDragClick + exDebugLayerDragCurrent + exDebugLayerDragDeltaX + exDebugLayerDragDeltaY + exDebugLayerDragDelta + exDebugLayerDragHighlight
exDebugLayerDragRotateCenter	32	Shows the rotation center of the dragging layer. The RotateCenterLayer , RotateCenterX and RotateCenterY properties determines the (x,y) rotation center, relative to specified layer.
exDebugLayerDragDeltaAngle64	64	Shows the delta angle. The DeltaAngle property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation.
exDebugLayerDragDeltaAngleMultiply	128	Adds lines to split equally the circle.
exDebugLayerDragRotate	483	Shortcut flag for rotate operation by dragging. It combines exDebugLayerDragClick + exDebugLayerDragCurrent + exDebugLayerDragRotateCenter + exDebugLayerDragDeltaAngle + exDebugLayerDragDeltaAngleMultiply + exDebugLayerDragHighlight.
exDebugLayerDragAll	-1	Includes all debug information.

constants DebugLayerEnum

The DebugLayerEnum type indicates the values of Debug property. Use the [Debug](#) property to display the layers in debug mode.

The following screen shot shows the control while Debug property is exDebugLayers:

The DebugLayerEnum type supports the following properties and method:

Name	Value	Description
exNoDebugLayer	0	No debug information is shown.
exDebugLayers	1	The control shows all layers in debug mode. The ShowLayers property indicates the only layers to be shown on the control. The exDebugLayers flag can be combined with the exDebugAutoScroll flag.
exDebugVisibleLayers	2	The control shows only visible layers in debug mode. The ShowLayers property indicates the only layers to be shown on the control. The exDebugVisibleLayers flag can be combined with the exDebugAutoScroll flag
exDebugAutoScroll	256	The user can scroll the layers into the debug view.

constants DefaultLayerPropertyEnum

The DefaultLayerPropertyEnum type specifies the properties of the layer, whose default value can be changed by the [DefaultLayer](#) property. Any call of the [DefaultLayer](#) property has effect for any new layer added to the control's collection. Changing the [DefaultLayer](#) property does not have any effect on existing layers. It does have effect on any new layer added to the control. The DefaultLayerPropertyEnum type supports the following values:

Name	Value	Description
exDefLayerVisible	0	Retrieves or sets a value indicating whether the layer is visible or hidden. Specifies the default value of the Visible property.
exDefLayerSelectable	1	Returns or sets a value that indicates whether the layer is selectable. Specifies the default value of the Selectable property.
exDefLayerLeft	16	Specifies the expression relative to the view, to determine the x-position to show the current layer on the control. Specifies the default value of the Left property.
exDefLayerTop	17	Specifies the expression relative to the view, to determine the y-position to show the current layer on the control. Specifies the default value of the Top property.
exDefLayerWidth	18	Specifies the expression relative to the view, to determine the width to show the current layer on the control. Specifies the default value of the Width property.
exDefLayerHeight	19	Specifies the expression relative to the view, to determine the height to show the current layer on the control. Specifies the default value of the Height property.
exDefLayerToolTip	20	Gets or sets a value (HTML tooltip) that's displayed once the cursor hovers the layer. Specifies the default value of the ToolTip property.
exDefLayerToolTipTitle	21	Gets or sets a value (title) that's displayed once the cursor hovers the layer. Specifies the default value of the ToolTipTitle property.
exDefLayerTransparency	22	Gets or sets a value that indicates percent of the transparency to display the layer. Specifies the default value of the Transparency property.

exDefLayerGrayscale	23	Returns or sets a value that indicates whether the layer is show as grayscale. Specifies the default value of the Grayscale property.
exDefLayerUserData	24	Indicates any extra data associated with the layer. Specifies the default value of the UserData property.
exDefLayerBrightness	128	Specifies the percent of brightness to apply to the layer (on all channels). Specifies the default value of the Brightness(exAllChannels) property.
exDefLayerBrightnessRed	129	Specifies the percent of brightness to apply to the layer (on red channel). Specifies the default value of the Brightness(exRedChannel) property.
exDefLayerBrightnessGreen	130	Specifies the percent of brightness to apply to the layer (on green channel). Specifies the default value of the Brightness(exGreenChannel) property.
exDefLayerBrightnessBlue	131	Specifies the percent of brightness to apply to the layer (on blue channel). Specifies the default value of the Brightness(exBlueChannel) property.
exDefLayerContrast	144	Specifies the percent of contrast to apply to the layer (on all channels). Specifies the default value of the Contrast(exAllChannels) property.
exDefLayerContrastRed	145	Specifies the percent of contrast to apply to the layer (on red channel). Specifies the default value of the Contrast(exRedChannel) property.
exDefLayerContrastGreen	146	Specifies the percent of contrast to apply to the layer (on green channel). Specifies the default value of the Contrast(exGreenChannel) property.
exDefLayerContrastBlue	147	Specifies the percent of contrast to apply to the layer (on blue channel). Specifies the default value of the Contrast(exBlueChannel) property.
exDefLayerOffsetX	160	Gets or sets a value that indicates x-offset of the layer. Specifies the default value of the OffsetX property.
exDefLayerOffsetY	161	Gets or sets a value that indicates x-offset of the layer. Specifies the default value of the OffsetX property.
exDefLayerDefaultOffsetX	162	Gets or sets a value that indicates the default x-offset of the layer. Specifies the default value of the

[DefaultOffsetX](#) property.

exDefLayerDefaultOffsetY	163	Gets or sets a value that indicates the default y-offset of the layer. Specifies the default value of the DefaultOffsetY property.
--------------------------	-----	--

exDefLayerOffsetXValid	164	Validates the x-offset value of the layer. Specifies the default value of the OffsetXValid property.
------------------------	-----	--

exDefLayerOffsetYValid	165	Validates the y-offset value of the layer. Specifies the default value of the OffsetYValid property.
------------------------	-----	--

exDefLayerValueToOffsetX	166	Specifies the expression to convert the value to x-offset. Specifies the default value of the ValueToOffsetX property.
--------------------------	-----	--

exDefLayerValueToOffsetY	167	Specifies the expression to convert the value to y-offset. Specifies the default value of the ValueToOffsetY property.
--------------------------	-----	--

exDefLayerOffsetToValue	168	Specifies the expression to convert the offsetx,offsety to value. Specifies the default value of the OffsetToValue property.
-------------------------	-----	--

exDefLayerRotateAngle	176	Specifies the angle to rotate the layer. Specifies the default value of the RotateAngle property.
-----------------------	-----	---

exDefLayerDefaultRotateAngle	177	Specifies the default angle to rotate the layer. Specifies the default value of the DefaultRotateAngle property.
------------------------------	-----	--

exDefLayerRotateAngleValid	178	Validates the rotation angle of the layer. Specifies the default value of the RotateAngleValid property.
----------------------------	-----	--

exDefLayerRotateCenterLayer	179	Indicates the index of the layer the rotation is around. If -1, the rotation is relative to the current layer. Specifies the default value of the RotateCenterLayer property.
-----------------------------	-----	---

exDefLayerRotateCenterX	180	Indicates the expression that determines the x-origin of the rotation point relative to the RotateCenterLayer layer. Specifies the default value of the RotateCenterX property.
-------------------------	-----	---

exDefLayerRotateCenterY	181	Indicates the expression that determines the y-origin of the rotation point relative to the RotateCenterLayer layer. Specifies the default value of the RotateCenterY property.
-------------------------	-----	---

exDefLayerValueToRotateAngle	182	Specifies the expression to convert the value to rotating angle. Specifies the default value of the
------------------------------	-----	---

[ValueToRotateAngle](#) property.

exDefLayerRotateAngleToValue 183

Specifies the expression to convert the rotating angle to value. Specifies the default value of the [RotateAngleToValue](#) property.

exDefLayerRotateClip 184

Specifies whether the layer's clipping region is rotated once the layer is rotated. Specifies the default value of the [RotateClip](#) property.

exDefLayerRotateType 185

Returns or sets a value that indicates whether the layer's rotation is performed fast, by shearing (high quality rotation), ... Specifies the default value of the [RotateType](#) property.

exDefLayerShowHandCursor 192

Returns or sets a value that indicates whether the hand cursor is shown when it hovers a visible / selectable / draggable layer. Specifies the default value of the [ShowHandCursor](#) property.

constants LayerClipTypeEnum

The LayerClipTypeEnum type specifies the clipping types currently any layer can support. The [Type](#) property specifies the type of the clipping the current layer supports. The Type property can be any combination of the following flags, which indicates intersection of them. The LayerClipTypeEnum type supports the following value:

Name	Value	Description
exLayerClipEmpty	0	No clipping is applied to the layer.
exLayerClipRectangle	1	Indicates that the ClipRectangle is applied on the layer.
exLayerClipRoundRectangle	2	Indicates that the ClipRoundRectangle is applied on the layer.
exLayerClipEllipse	4	Indicates that the ClipEllipse is applied on the layer.
exLayerClipPie	8	Indicates that the ClipPie is applied on the layer.
exLayerClipPolygon	16	Indicates that the ClipPolygon is applied on the layer.
exLayerClipPicture	32	Indicates that the ClipPicture is applied on the layer.

constants LayerUpdateEnum

The LayerUpdateEnum type specifies the way the control clips its content. The control support transparent form, or in other words, displaying the control's itself without its form behind.

Currently, the control supports two type of clippings:

- by region clipping, using the [LayerClipTo](#) property
- by layering, using the [LayerUpdate](#) property

The LayerUpdateEnum type supports the following values:

Name	Value	Description
exLayerUpdateControl	0	By default, the control updates its content.
exLayerUpdateParent	1	Updates the parent's device, to clip the control inside.
exLayerUpdateScreen	2	Updates the screen's device, to clip the control inside.

constants OnDragLayerEnum

The OnDragLayerEnum type indicates the operation a layer can perform when user clicks and drags it. The [OnDrag](#) property indicates the action to be performed when the user drags the layer. The OnDragLayerEnum type supports the following value:

Name	Value	Description
exDoNothing	0	Nothing happens if the user drags the layer.
exDoMove	1	The layer is moved while dragging. The layer's OffsetX and OffsetY indicates the current (x,y) position of the layer.
exDoRotate	2	The layer is rotated while dragging. The RotateAngle property indicates the currently rotation angle.
exDoRotamove	3	The layer is moved by rotation while dragging. The RotateAngle property indicates the currently rotation angle. In this case, the layer's RotamoveOffsetX / RotamoveOffsetY property indicates the current (x,y) position of the layer.

constants **PictureDisplayEnum**

Specifies how a picture object is displayed. The [DisplayAs](#) property retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background. The PictureDisplayEnum type supports the following values:

Name	Value	Description
UpperLeft	0	Aligns the picture to the upper left corner.
UpperCenter	1	Centers the picture on the upper edge.
UpperRight	2	Aligns the picture to the upper right corner.
MiddleLeft	16	Aligns horizontally the picture on the left side, and centers the picture vertically.
MiddleCenter	17	Puts the picture on the center of the source.
MiddleRight	18	Aligns horizontally the picture on the right side, and centers the picture vertically.
LowerLeft	32	Aligns the picture to the lower left corner.
LowerCenter	33	Centers the picture on the lower edge.
LowerRight	34	Aligns the picture to the lower right corner.
Tile	48	Tiles the picture on the source.
Stretch	49	The picture is resized to fit the source.

constants PropertyLayerCaptionEnum

The PropertyLayerCaptionEnum type holds properties of the HTML caption that can be displayed on the control, or on the layer's foreground. Any of the following properties can be used to display a HTML caption:

- [Caption](#) property specifies the caption to be shown on the control's foreground.
- [ExtraCaption](#) property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

The PropertyLayerCaptionEnum type supports the following value:

Name	Value	Description
exLayerCaption	0	Indicates the HTML caption to be displayed on the caption. By default, the exLayerCaption is empty. You can use the exLayerCaptionWordWrap to display the caption on multiple lines. The exLayerCaption supports built-in HTML format as listed here . (string expression)
exLayerCaptionBackColor	1	Indicates the layer's background color. By default, the exLayerCaptionBackColor property is -1, which indicates that no background color is applied. The last 7 bits in the high significant byte of the color indicates the identifier of the skin being used. You can use the <bgcolor> HTML tag in the exLayerCaption to specify a different background color for a portion of the text. Use the Add method to add new skins to the control. If you need to remove the skin appearance from a part of the control you need to reset the last 7 bits in the high significant byte of the color being applied to the background's part. (long expression)

Indicates the layer's foreground color. By default, the exLayerCaptionForeColor property is -1, which

exLayerCaptionForeColor	2	indicates that no foreground color is applied. You can use the <fgcolor> HTML tag in the exLayerCaption to specify a different foreground color for a portion of the text.
-------------------------	---	--

(long expression)

exLayerCaptionAnchor	3	Specifies the side of the host where the caption is anchored. By default, the exLayerCaptionAnchor property is 1 (exAnchorTop), that indicates that the caption is anchored to the top side of its host. You can use the exLayerCaptionLeft, exLayerCaptionTop, exLayerCaptionWidth and exLayerCaptionHeight to display the caption at a different position relative to its original position.
----------------------	---	--

([AnchorEnum](#) type).

Specifies the expression to determine the x-position to show the caption, relative to its current position. By default, the exLayerCaptionLeft property is "0", which indicates that the caption is displayed at it's original position (horizontal axis), determined by the exLayerCaptionAnchor. You can use the exLayerCaptionAnchor property to anchor the caption to a different side of the host.

The property supports the following keywords:

exLayerCaptionLeft	4	<ul style="list-style-type: none"> • twidht, indicates the width required to fully display the caption • theight, indicates the height required to fully display the caption • width, indicates the width of the layer (if it is applied to the layer's foreground Foreground.Caption or Foreground.ExtraCaption), or of the control (if it is applied to the control's foreground Caption or ExtraCaption) • height, indicates the height of the layer (if it is applied to the layer's foreground Foreground.Caption or Foreground.ExtraCaption), or of the control (if
--------------------	---	--

it is applied to the control's foreground [Caption](#) or [ExtraCaption](#))

The property supports predefined constants, operators and functions as described [here](#) .

(string expression)

Specifies the expression to determine the y-position to show the caption, relative to its current position. By default, the exLayerCaptionTop property is "0", which indicates that the caption is displayed at it's original position (vertical axis), determined by the exLayerCaptionAnchor. You can use the exLayerCaptionAnchor property to anchor the caption to a different side of the host.

The property supports the following keywords:

- **twidth**, indicates the width required to fully display the caption
- **theight**, indicates the height required to fully display the caption
- **width**, indicates the width of the layer (if it is applied to the layer's foreground [Foreground.Caption](#) or [Foreground.ExtraCaption](#)), or of the control (if it is applied to the control's foreground [Caption](#) or [ExtraCaption](#))
- **height**, indicates the height of the layer (if it is applied to the layer's foreground [Foreground.Caption](#) or [Foreground.ExtraCaption](#)), or of the control (if it is applied to the control's foreground [Caption](#) or [ExtraCaption](#))

The property supports predefined constants, operators and functions as described [here](#) .

(string expression)

Specifies the expression to determine the width to show the caption, relative to its current width. By

exLayerCaptionTop

5

default, the `exLayerCaptionWidth` property is "twidth", which indicates that the caption is displayed on its full width. You can use the `exLayerCaptionAnchor` property to anchor the caption to a different side of the host.

The property supports the following keywords:

- **twidth**, indicates the width required to fully display the caption
- **theight**, indicates the height required to fully display the caption
- **width**, indicates the width of the layer (if it is applied to the layer's foreground [Foreground.Caption](#) or [Foreground.ExtraCaption](#)), or of the control (if it is applied to the control's foreground [Caption](#) or [ExtraCaption](#))
- **height**, indicates the height of the layer (if it is applied to the layer's foreground [Foreground.Caption](#) or [Foreground.ExtraCaption](#)), or of the control (if it is applied to the control's foreground [Caption](#) or [ExtraCaption](#))

`exLayerCaptionWidth`

6

The property supports predefined constants, operators and functions as described [here](#) .

(string expression)

Specifies the expression to determine the height to show the caption, relative to its current height. By default, the `exLayerCaptionHeight` property is "theight", which indicates that the caption is displayed on its full height. You can use the `exLayerCaptionAnchor` property to anchor the caption to a different side of the host.

The property supports the following keywords:

- **twidth**, indicates the width required to fully display the caption
- **theight**, indicates the height required to fully display the caption

exLayerCaptionHeight

7

- **width**, indicates the width of the layer (if it is applied to the layer's foreground [Foreground.Caption](#) or [Foreground.ExtraCaption](#)), or of the control (if it is applied to the control's foreground [Caption](#) or [ExtraCaption](#))
- **height**, indicates the height of the layer (if it is applied to the layer's foreground [Foreground.Caption](#) or [Foreground.ExtraCaption](#)), or of the control (if it is applied to the control's foreground [Caption](#) or [ExtraCaption](#))

The property supports predefined constants, operators and functions as described [here](#) .

(string expression)

exLayerCaptionWordWrap

8

Indicates whether a multiline caption automatically wraps words to the beginning of the next line when necessary. By default, the exLayerCaptionWordWrap property is False.

(boolean expression)

exLayerCaptionBackgroundEx0

Indicates Unlimited options to show any HTML text, images, colors, EBNs, patterns, frames anywhere on the layer's background, using EBN String Format. A short description of the EBN String Format is described [here](#), or a full description of the EBN String Format can be found [here](#).

(string expression)

exLayerCaptionVisibleFront

10

Specifies whether the caption is shown in front. By default, the exLayerCaptionVisibleFront property is True, which indicates that the caption is shown in front. Use the exLayerCaptionVisibleFront property to display the caption on the layer's background, if the exLayerCaptionVisibleFront property is False.

(boolean expression)

The exLayerCaption supports built-in HTML tags as follow:

- ** ... ** displays the text in **bold**
- **<i> ... </i>** displays the text in *italics*
- **<u> ... </u>** underlines the text
- **<s> ... </s>** Strike-through text
- **<a id;options> ... ** displays an [anchor](#) element that can be clicked. An anchor is a piece of text or some other object (for example an image) which marks the beginning and/or the end of a hypertext link. The <a> element is used to mark that piece of text (or inline image), and to give its hypertextual relationship to other documents. The control fires the *AnchorClick(AnchorID, Options)* event when the user clicks the anchor element. The *FormatAnchor* property customizes the visual effect for anchor elements.
- ** ... ** displays portions of text with a different font and/or different size. For instance, the "**bit**" draws the bit text using the Tahoma font, on size 12 pt. If the name of the font is missing, and instead size is present, the current font is used with a different size. For instance, "**bit**" displays the bit text using the current font, but with a different size.
- **<fgcolor rrggbb> ... </fgcolor>** or **<fgcolor=rrggb> ... </fgcolor>** displays text with a specified **foreground** color. The rr/gg/bb represents the red/green/blue values of the color in hexa values.
- **<bgcolor rrggbb> ... </bgcolor>** or **<bgcolor=rrggb> ... </bgcolor>** displays text with a specified **background** color. The rr/gg/bb represents the red/green/blue values of the color in hexa values.
- **<solidline rrggbb> ... </solidline>** or **<solidline=rrggb> ... </solidline>** draws a solid-line on the bottom side of the current text-line, of specified RGB color. The <solidline> ... </solidline> draws a black solid-line on the bottom side of the current text-line. The rr/gg/bb represents the red/green/blue values of the color in hexa values.
- **<dotline rrggbb> ... </dotline>** or **<dotline=rrggb> ... </dotline>** draws a dot-line on the bottom side of the current text-line, of specified RGB color. The <dotline> ... </dotline> draws a black dot-line on the bottom side of the current text-line. The rr/gg/bb represents the red/green/blue values of the color in hexa values.
- **<upline> ... </upline>** draws the line on the top side of the current text-line (requires <solidline> or <dotline>).
- **<r>** right aligns the text
- **<c>** centers the text
- **
** forces a line-break
- **number[:width]** inserts an icon inside the text. The number indicates the index of the icon being inserted. Use the Images method to assign a list of icons to your chart. The last 7 bits in the high significant byte of the number expression indicates the identifier of the skin being used to paint the object. Use the [Add](#) method to add new skins to the control. If you need to remove the skin appearance from a part

of the control you need to reset the last 7 bits in the high significant byte of the color being applied to the part. The width is optional and indicates the width of the icon being inserted. Using the width option you can overwrite multiple icons getting a nice effect. By default, if the width field is missing, the width is 18 pixels.

- **key[:width]** inserts a custom size picture into the text being previously loaded using the HTMLPicture property. The Key parameter indicates the key of the picture being displayed. The Width parameter indicates a custom size, if you require to stretch the picture, else the original size of the picture is used.
- **&** glyph characters as **&**; (&), **<**; (<), **>**; (>), **"**; (") and **&#number;**; (the character with specified code), For instance, the **€** displays the EUR character. The **&** ampersand is only recognized as markup when it is followed by a known letter or a #character and a digit. For instance if you want to display **bold** in HTML caption you can use **>bold**;
- **<off offset> ... </off>** defines the vertical offset to display the text/element. The offset parameter defines the offset to display the element. This tag is inheritable, so the offset is keep while the associated **</off>** tag is found. You can use the **<off offset>** HTML tag in combination with the **** to define a smaller or a larger font to be displayed. For instance: "Text with **<off 6>**subscript" displays the text such as: Text with subscript The "Text with **<off -6>**superscript" displays the text such as: Text with superscript
- **<gra rrggbb;mode;blend> ... </gra>** defines a gradient text. The text color or **<fgcolor>** defines the starting gradient color, while the rr/gg/bb represents the red/green/blue values of the ending color, 808080 if missing as gray. The mode is a value between 0 and 4, 1 if missing, and blend could be 0 or 1, 0 if missing. The **** HTML tag can be used to define the height of the font. Any of the rrggbb, mode or blend field may not be specified. The **<gra>** with no fields, shows a vertical gradient color from the current text color to gray (808080). For instance the "**<gra FFFFFFFF;1;1>**gradient-center**</gra>**" generates the following picture:

gradient-center

- **<out rrggbb;width> ... </out>** shows the text with outlined characters, where rr/gg/bb represents the red/green/blue values of the outline color, 808080 if missing as gray, width indicates the size of the outline, 1 if missing. The text color or **<fgcolor>** defines the color to show the inside text. The **** HTML tag can be used to define the height of the font. For instance the "**<out 000000>**
<fgcolor=FFFFFF>outlined**</fgcolor></out>**" generates the following picture:

outlined

- **<sha rrggbb;width;offset> ... </sha>** define a text with a shadow, where rr/gg/bb represents the red/green/blue values of the shadow color, 808080 if missing as gray, width indicates the size of shadow, 4 if missing, and offset indicates the offset from the origin to display the text's shadow, 2 if missing. The text color or **<fgcolor>** defines the

color to show the inside text. The HTML tag can be used to define the height of the font. For instance the "<sha>shadow</sha>" generates the following picture:

shadow

or "<sha 404040;5;0><fgcolor=FFFFFF>outline anti-aliasing</fgcolor></sha>" gets:

outline anti-aliasing

The property supports predefined constants, operators and functions as listed bellow:

The constants are (DPI-Aware components):

- **dpi** (DPI constant), specifies the current DPI setting. and it indicates the minimum value between **dpix** and **dpiy** constants. For instance, if current DPI setting is 100%, the dpi constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpi returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%
- **dpix** (DPIX constant), specifies the current DPI setting on x-scale. For instance, if current DPI setting is 100%, the dpix constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpix returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%
- **dpiy** (DPIY constant), specifies the current DPI setting on y-scale. For instance, if current DPI setting is 100%, the dpiy constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpiy returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%

The supported binary arithmetic operators are:

- * (multiplicity operator), priority 5
- / (divide operator), priority 5
- **mod** (reminder operator), priority 5
- + (addition operator), priority 4 (concatenates two strings, if one of the operands is of string type)
- - (subtraction operator), priority 4

The supported unary boolean operators are:

- **not** (not operator), priority 3 (high priority)

The supported binary boolean operators are:

- **or** (or operator), priority 2
- **and** (or operator), priority 1

The supported binary boolean operators, all these with the same priority 0, are :

- **<** (less operator)
- **<=** (less or equal operator)
- **=** (equal operator)
- **!=** (not equal operator)
- **>=** (greater or equal operator)
- **>** (greater operator)

The supported binary range operators, all these with the same priority 5, are :

- **MIN** (min operator), indicates the minimum value, so a **MIN** b returns the value of a, if it is less than b, else it returns b. For instance, the expression value MIN 10 returns always a value greater than 10.
- **MAX** (max operator), indicates the maximum value, so a **MAX** b returns the value of a, if it is greater than b, else it returns b. For instance, the expression value MAX 100 returns always a value less than 100.

The supported binary operators, all these with the same priority 0, are :

- **:= (Store operator)**, stores the result of expression to variable. The syntax for := operator is

variable := expression

where variable is a integer between 0 and 9. You can use the **:=** operator to restore any stored variable (please make the difference between **:=** and **=:**). For instance, `(0:=dbl(value)) = 0 ? "zero" : :=:0`, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the **:=** and **=:** are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

- **=: (Restore operator)**, restores the giving variable (previously saved using the store operator). The syntax for **=:** operator is

=: variable

where variable is a integer between 0 and 9. You can use the **=:** operator to store the value of any expression (please make the difference between **:=** and **=:**). For instance, `(0:=dbl(value)) = 0 ? "zero" : :=:0`, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the **:=** and **=:**

are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

The supported ternary operators, all these with the same priority 0, are :

- **? (Immediate If operator)**, returns and executes one of two expressions, depending on the evaluation of an expression. The syntax for ? operator is

expression ? true_part : false_part

, while it executes and returns the true_part if the expression is true, else it executes and returns the false_part. For instance, the `%0 = 1 ? 'One' : (%0 = 2 ? 'Two' : 'not found')` returns 'One' if the value is 1, 'Two' if the value is 2, and 'not found' for any other value. A n-ary equivalent operation is the `case()` statement, which is available in newer versions of the component.

The supported n-ary operators are (with priority 5):

- **array (at operator)**, returns the element from an array giving its index (0 base). The array operator returns empty if the element is found, else the associated element in the collection if it is found. The syntax for array operator is

expression array (c1,c2,c3,...cn)

, where the c1, c2, ... are constant elements. The constant elements could be numeric, date or string expressions. For instance the `month(value)-1 array ('J','F','M','A','M','Jun','J','A','S','O','N','D')` is equivalent with `month(value)-1 case (default:"; 0:'J';1:'F';2:'M';3:'A';4:'M';5:'Jun';6:'J';7:'A';8:'S';9:'O';10:'N';11:'D')`.

- **in (include operator)**, specifies whether an element is found in a set of constant elements. The in operator returns -1 (True) if the element is found, else 0 (false) is retrieved. The syntax for in operator is

expression in (c1,c2,c3,...cn)

, where the c1, c2, ... are constant elements. The constant elements could be numeric, date or string expressions. For instance the `value in (11,22,33,44,13)` is equivalent with `(expression = 11) or (expression = 22) or (expression = 33) or (expression = 44) or (expression = 13)`. The in operator is not a time consuming as the equivalent or version is, so when you have large number of constant elements it is recommended using the in operator. Shortly, if the collection of elements has 1000 elements the in operator could take up to 8 operations in order to find if an element fits the set, else if the or statement is used, it could take up to 1000 operations to check, so by far, the in operator could save time on finding elements within a collection.

- **switch** (*switch operator*), returns the value being found in the collection, or a predefined value if the element is not found (default). The syntax for *switch* operator is

expression switch (default,c1,c2,c3,...,cn)

, where the *c1*, *c2*, ... are constant elements, and the *default* is a constant element being returned when the element is not found in the collection. The constant elements could be numeric, date or string expressions. The equivalent syntax is "%0 = c 1 ? c 1 : (%0 = c 2 ? c 2 : (... ? . : default))". The *switch* operator is very similar with the *in* operator excepts that the first element in the switch is always returned by the statement if the element is not found, while the returned value is the value itself instead -1. For instance, the %0 *switch* ('not found',1,4,7,9,11) gets 1, 4, 7, 9 or 11, or 'not found' for any other value. As the *in* operator the *switch* operator uses binary searches for fitting the element, so it is quicker than *iif* (immediate if operator) alternative.

- **case()** (*case operator*) returns and executes one of *n* expressions, depending on the evaluation of the expression (*IIF* - immediate IF operator is a binary *case()* operator). The syntax for *case()* operator is:

expression case ([default : default_expression ;] c1 : expression1 ; c2 : expression2 ; c3 : expression3 ;....)

If the default part is missing, the *case()* operator returns the value of the expression if it is not found in the collection of cases (*c1*, *c2*, ...). For instance, if the value of expression is not any of *c1*, *c2*, the *default_expression* is executed and returned. If the value of the expression is *c1*, then the *case()* operator executes and returns the *expression1*. The *default*, *c1*, *c2*, *c3*, ... must be constant elements as numbers, dates or strings. For instance, the *date(shortdate(value)) case (default:0 ; #1/1/2002#:1 ; #2/1/2002#:1; #4/1/2002#:1; #5/1/2002#:1)* indicates that only #1/1/2002#, #2/1/2002#, #4/1/2002# and #5/1/2002# dates returns 1, since the others returns 0. For instance the following sample specifies the hour being non-working for specified dates: *date(shortdate(value)) case(default:0;#4/1/2009# : hour(value) >= 6 and hour(value) <= 12 ; #4/5/2009# : hour(value) >= 7 and hour(value) <= 10 or hour(value) in(15,16,18,22); #5/1/2009# : hour(value) <= 8)* statement indicates the working hours for dates as follows:

- #4/1/2009#, from hours 06:00 AM to 12:00 PM
- #4/5/2009#, from hours 07:00 AM to 10:00 AM and hours 03:00PM, 04:00PM, 06:00PM and 10:00PM
- #5/1/2009#, from hours 12:00 AM to 08:00 AM

The *in*, *switch* and *case()* use binary search to look for elements so they are faster than using *iif* and *or* expressions. Obviously, the priority of the operations inside the expression is

determined by () parenthesis and the priority for each operator.

The supported conversion unary operators are:

- **type** (unary operator) retrieves the type of the object. For instance *type(%1) = 8* specifies the cells (on the column 1) that contains string values.

Here's few predefined types:

- 0 - empty (not initialized)
 - 1 - null
 - 2 - short
 - 3 - long
 - 4 - float
 - 5 - double
 - 6 - currency
 - 7 - date
 - 8 - string
 - 9 - object
 - 10 - error
 - 11 - boolean
 - 12 - variant
 - 13 - any
 - 14 - decimal
 - 16 - char
 - 17 - byte
 - 18 - unsigned short
 - 19 - unsigned long
 - 20 - long on 64 bits
 - 21 - unsigned long on 64 bites
- **str** (unary operator) converts the expression to a string. The str operator converts the expression to a string. For instance, the *str(-12.54)* returns the string "-12.54".
 - **dbl** (unary operator) converts the expression to a number. The dbl operator converts the expression to a number. For instance, the *dbl("12.54")* returns 12.54
 - **date** (unary operator) converts the expression to a date, based on your regional settings. For instance, the *date(``)* gets the current date (no time included), the *date(`now`)* gets the current date-time, while the *date("01/01/2001")* returns #1/1/2001#
 - **dateS** (unary operator) converts the string expression to a date using the format MM/DD/YYYY HH:MM:SS. For instance, the *dateS("01/01/2001 14:00:00")* returns #1/1/2001 14:00:00#

Other known operators for numbers are:

- **int** (unary operator) retrieves the integer part of the number. For instance, the *int(12.54)* returns 12
- **round** (unary operator) rounds the number ie 1.2 gets 1, since 1.8 gets 2. For instance, the *round(12.54)* returns 13
- **floor** (unary operator) returns the largest number with no fraction part that is not greater than the value of its argument. For instance, the *floor(12.54)* returns 12
- **abs** (unary operator) retrieves the absolute part of the number ie -1 gets 1, 2 gets 2. For instance, the *abs(-12.54)* returns 12.54
- **sin** (unary operator) returns the sine of an angle of x radians. For instance, the *sin(3.14)* returns 0.001593.
- **cos** (unary operator) returns the cosine of an angle of x radians. For instance, the *cos(3.14)* returns -0.999999.
- **asin** (unary operator) returns the principal value of the arc sine of x, expressed in radians. For instance, the *2*asin(1)* returns the value of PI.
- **acos** (unary operator) returns the principal value of the arc cosine of x, expressed in radians. For instance, the *2*acos(0)* returns the value of PI
- **sqrt** (unary operator) returns the square root of x. For instance, the *sqrt(81)* returns 9.
- **currency** (unary operator) formats the giving number as a currency string, as indicated by the control panel. For instance, *currency(value)* displays the value using the current format for the currency ie, 1000 gets displayed as \$1,000.00, for US format.
- value **format** 'flags' (binary operator) formats the value with specified flags. If flags is empty, the number is displayed as shown in the field "Number" in the "Regional and Language Options" from the Control Panel. For instance the *1000 format "* displays 1,000.00 for English format, while 1.000,00 is displayed for German format. *1000 format '2|.|3|,'* will always displays 1,000.00 no matter of settings in the control panel. If formatting the number fails for some invalid parameter, the value is displayed with no formatting.

The ' flags' for format operator is a list of values separated by | character such as '*NumDigits|DecimalSep|Grouping|ThousandSep|NegativeOrder|LeadingZero*' with the following meanings:

- *NumDigits* - specifies the number of fractional digits, If the flag is missing, the field "No. of digits after decimal" from "Regional and Language Options" is using.
- *DecimalSep* - specifies the decimal separator. If the flag is missing, the field "Decimal symbol" from "Regional and Language Options" is using.
- *Grouping* - indicates the number of digits in each group of numbers to the left of the decimal separator. Values in the range 0 through 9 and 32 are valid. The most significant grouping digit indicates the number of digits in the least significant group immediately to the left of the decimal separator. Each subsequent grouping digit indicates the next significant group of digits to the left of the previous group. If the last value supplied is not 0, the remaining groups repeat the last group. Typical

examples of settings for this member are: 0 to group digits as in 123456789.00; 3 to group digits as in 123,456,789.00; and 32 to group digits as in 12,34,56,789.00. If the flag is missing, the field "Digit grouping" from "Regional and Language Options" indicates the grouping flag.

- *ThousandSep* - specifies the thousand separator. If the flag is missing, the field "Digit grouping symbol" from "Regional and Language Options" is using.
- *NegativeOrder* - indicates the negative number mode. If the flag is missing, the field "Negative number format" from "Regional and Language Options" is using. The valid values are 0, 1, 2, 3 and 4 with the following meanings:
 - 0 - Left parenthesis, number, right parenthesis; for example, (1.1)
 - 1 - Negative sign, number; for example, -1.1
 - 2 - Negative sign, space, number; for example, - 1.1
 - 3 - Number, negative sign; for example, 1.1-
 - 4 - Number, space, negative sign; for example, 1.1 -
- *LeadingZero* - indicates if leading zeros should be used in decimal fields. If the flag is missing, the field "Display leading zeros" from "Regional and Language Options" is using. The valid values are 0, 1

Other known operators for strings are:

- **len** (unary operator) retrieves the number of characters in the string. For instance, the *len("Mihai")* returns 5.
- **lower** (unary operator) returns a string expression in lowercase letters. For instance, the *lower("MIHAI")* returns "mihai"
- **upper** (unary operator) returns a string expression in uppercase letters. For instance, the *upper("mihai")* returns "MIHAI"
- **proper** (unary operator) returns from a character expression a string capitalized as appropriate for proper names. For instance, the *proper("mihai")* returns "Mihai"
- **ltrim** (unary operator) removes spaces on the left side of a string. For instance, the *ltrim(" mihai")* returns "mihai"
- **rtrim** (unary operator) removes spaces on the right side of a string. For instance, the *rtrim("mihai ")* returns "mihai"
- **trim** (unary operator) removes spaces on both sides of a string. For instance, the *trim(" mihai ")* returns "mihai"
- **reverse** (unary operator) reverses the order of the characters in the string a. For instance, the *reverse("Mihai")* returns "iahIM"
- **startswith** (binary operator) specifies whether a string starts with specified string (0 if not found, -1 if found). For instance *"Mihai" startswith "Mi"* returns -1
- **endwith** (binary operator) specifies whether a string ends with specified string (0 if not found, -1 if found). For instance *"Mihai" endwith "ai"* returns -1
- **contains** (binary operator) specifies whether a string contains another specified string (0 if not found, -1 if found). For instance *"Mihai" contains "ha"* returns -1

- **left** (binary operator) retrieves the left part of the string. For instance *"Mihai" left 2* returns "Mi".
- **right** (binary operator) retrieves the right part of the string. For instance *"Mihai" right 2* returns "ai"
- a **lfind** b (binary operator) The a lfind b (binary operator) searches the first occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" lfind "C"* returns 2
- a **rfind** b (binary operator) The a rfind b (binary operator) searches the last occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" rfind "C"* returns 5.
- a **mid** b (binary operator) retrieves the middle part of the string a starting from b (1 means first position, and so on). For instance *"Mihai" mid 2* returns "ihai"
- a **count** b (binary operator) retrieves the number of occurrences of the b in a. For instance *"Mihai" count "i"* returns 2.
- a **replace b with c** (double binary operator) replaces in a the b with c, and gets the result. For instance, the *"Mihai" replace "i" with ""* returns "Mha" string, as it replaces all "i" with nothing.
- a **split** b, splits the a using the separator b, and returns an array. For instance, the *weekday(value) array 'Sun Mon Thu Wed Thu Fri Sat' split ' '* gets the weekday as string. This operator can be used with the array.

Other known operators for dates are:

- **time** (unary operator) retrieves the time of the date in string format, as specified in the control's panel. For instance, the *time(#1/1/2001 13:00#)* returns "1:00:00 PM"
- **timeF** (unary operator) retrieves the time of the date in string format, as "HH:MM:SS". For instance, the *timeF(#1/1/2001 13:00#)* returns "13:00:00"
- **shortdate** (unary operator) formats a date as a date string using the short date format, as specified in the control's panel. For instance, the *shortdate(#1/1/2001 13:00#)* returns "1/1/2001"
- **shortdateF** (unary operator) formats a date as a date string using the "MM/DD/YYYY" format. For instance, the *shortdateF(#1/1/2001 13:00#)* returns "01/01/2001"
- **dateF** (unary operator) converts the date expression to a string expression in "MM/DD/YYYY HH:MM:SS" format. For instance, the *dateF(#01/01/2001 14:00:00#)* returns #01/01/2001 14:00:00#
- **longdate** (unary operator) formats a date as a date string using the long date format, as specified in the control's panel. For instance, the *longdate(#1/1/2001 13:00#)* returns "Monday, January 01, 2001"
- **year** (unary operator) retrieves the year of the date (100,...,9999). For instance, the *year(#12/31/1971 13:14:15#)* returns 1971
- **month** (unary operator) retrieves the month of the date (1, 2,...,12). For instance, the

month(#12/31/1971 13:14:15#) returns 12.

- **day** (unary operator) retrieves the day of the date (1, 2,...,31). For instance, the *day(#12/31/1971 13:14:15#)* returns 31
- **yearday** (unary operator) retrieves the number of the day in the year, or the days since January 1st (0, 1,...,365). For instance, the *yearday(#12/31/1971 13:14:15#)* returns 365
- **weekday** (unary operator) retrieves the number of days since Sunday (0 - Sunday, 1 - Monday,..., 6 - Saturday). For instance, the *weekday(#12/31/1971 13:14:15#)* returns 5.
- **hour** (unary operator) retrieves the hour of the date (0, 1, ..., 23). For instance, the *hour(#12/31/1971 13:14:15#)* returns 13
- **min** (unary operator) retrieves the minute of the date (0, 1, ..., 59). For instance, the *min(#12/31/1971 13:14:15#)* returns 14
- **sec** (unary operator) retrieves the second of the date (0, 1, ..., 59). For instance, the *sec(#12/31/1971 13:14:15#)* returns 15

The Exontrol's [eXPression](#) component is a syntax-editor that helps you to define, view, edit and evaluate expressions. Using the eXPression component you can easily view or check if the expression you have used is syntactically correct, and you can evaluate what is the result you get giving different values to be tested. The Exontrol's eXPression component can be used as an user-editor, to configure your applications.

The EBN String Format syntax in BNF notation is defined like follows:

```
<EBN> ::= <elements> | <root> "(" [<elements>] ")"
<elements> ::= <element> [ "," <elements> ]
<root> ::= "root" [ <attributes> ] | [ <attributes> ]
<element> ::= <anchor> [ <attributes> ] [ "(" [<elements>] ")" ]
<anchor> ::= "none" | "left" | "right" | "client" | "top" | "bottom"
<attributes> ::= "[" [<client> "," <attribute> [ "," <attributes> ] "]"
<client> ::= <expression> | <expression> "," <expression> "," <expression> ","
<expression>
<expression> ::= <number> | <number> "%"
<attribute> ::= <bgcolor> | <text> | <wordwrap> | <align> | <pattern> |
<patterncolor> | <frame> | <framethick> | <data> | <others>
<equal> ::= "="
<digit> ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
<decimal> ::= <digit> <decimal>
<hexadigit> ::= <digit> | "A" | "B" | "C" | "D" | "E" | "F"
<hexa> ::= <hexadigit> <hexa>
<number> ::= <decimal> | "0x" <hexa>
<color> ::= <rgbcolor> | number
<rgbcolor> ::= "RGB" "(" <number> "," <number> "," <number> ")"
<string> ::= "\"" <characters> "\"" | "\"" <characters> "\"" | " " <characters> "
<characters> ::= <char> | <characters>
<char> ::= <any_character_excepts_null>
<bgcolor> ::= "back" <equal> <color>
<text> ::= "text" <equal> <string>
<align> ::= "align" <equal> <number>
<pattern> ::= "pattern" <equal> <number>
<patterncolor> ::= "patterncolor" <equal> <color>
<frame> ::= "frame" <equal> <color>
<data> ::= "data" <equal> <number> | <string>
<framethick> ::= "framethick"
<wordwrap> ::= "wordwrap"
```

Others like: pic, stretch, hstretch, vstretch, transparent, from, to are reserved for future use only.

Easy samples:

- "[pattern=6]", shows the BDiagonal pattern on the object's background.

- "[frame=RGB(255,0,0),framethick]", draws a red thick-border around the object.

- "[frame=RGB(255,0,0),framethick,pattern=6,patterncolor=RGB(255,0,0)]", draws a red thick-border around the object, with a patten inside.

- "[[patterncolor=RGB(255,0,0)]
(none[(4,4,100%-8,100%-8),pattern=0x006,patterncolor=RGB(255,0,0),frame=RGB(255,0,0),framethick])]", draws a red thick-border around the object, with a patten inside, with a 4-pixels wide padding:

- "top[4,back=RGB(0,0,255)]", draws a blue line on the top side of the object's background, of 4-pixels wide.

- "[text=`caption`,align=0x22]", shows the caption string aligned to the bottom-right side of the object's background.

- "[text=`flag`,align=0x11]" shows the flag picture and the sweden string aligned to the bottom side of the object.

- "left[10,back=RGB(255,0,0)]", draws a red line on the left side of the object's background, of 10-pixels wide.

- "bottom[50%,pattern=6,frame]", shows the BDiagonal pattern with a border around on the lower-half part of the object's background.

- "root[text=`caption 2` ,align=0x22](client[text=`caption 1` ,align=0x20])", shows the caption **1** aligned to the bottom-left side, and the caption **2** to the bottom-right side

Now, lets say we have the following request to layout the colors on the objects:

We define the BackgroundExt property such as "top[30%,back=RGB(253,218,101)],client[back=RGB(91,157,210)],none[(0%,0%,10%,100%)(top[90%,back=RGB(0,0,0)])]", and it looks as:

To String: `top[30%,back=RGB(253,218,101)],client[back=RGB(91,157,210)],none[(0%,0%,10%,100%)](top[90%,back=RGB(0,0,0)])`

Root

Top_{30%}

Client

None_{0%,0%,10%,100%}

Top_{90%}

Visual representation of the BackgroundExt property definition. It shows a hierarchy of layers: Root, Top_{30%}, Client, None_{0%,0%,10%,100%}, and Top_{90%}. The diagram shows a black corner on the left, a yellow top section, and a blue bottom section, with a small blue area at the bottom left.

so, if we apply to our object we got:

Now, lets say we have the following request to layout the colors on the objects:

We define BackgroundExt property such as "left[10%]

(top[90%,back=RGB(0,0,0)]),top[30%,back=RGB(254,217,102)],client[back=RGB(91,156,212)] and it looks as:

so, if we apply to our object we got:

constants RotateTypeEnum

The RotateTypeEnum type indicates the type of rotation currently, the control supports. The [RotateType](#) property returns or sets a value that indicates whether the layer's rotation is performed fast, by shearing (high quality rotation), ... The RotateTypeEnum type supports the following values.

Name	Value	Description
exRotateFast	0	This is the default value. It is the fastest method compared with others but the images is not as smooth as possible.
exRotateByShear	1	The method also called "Rotation Through Shearing", unlike traditional rotation of images, where every n'th pixel is sampled and copied to the result image, this template provides much more accurate image rotation features (weighing the pixels).
exRotateBilinearInterpolation	2	This method also called "Rotation by Bilinear Interpolation", is fast, and produces perfect rotation images.

constants SmoothPropertyEnum

The SmoothPropertyEnum type specifies the properties of the layer that can be changed gradually. The [AllowSmoothChange](#) property specifies the properties of the layers that support smooth change. The SmoothPropertyEnum type supports the following values.

Name	Value	Description
exSmoothChangeless	0	The change of any of the following properties is not gradually.
exLayerTransparency	1	Transparency , Gets or sets a value that indicates percent of the transparency to display the layer.
exLayerBrightness	2	Brightness , Specifies the percent of brightness to apply to the layer.
exLayerContrast	4	Contrast , Specifies the percent of contrast to apply to the layer.

Appearance object

The component lets the user changes its visual appearance using **skins**, each one providing an additional visual experience that enhances viewing pleasure. Skins are relatively easy to build and put on any part of the control. The Appearance object holds a collection of skins. The Appearance object supports the following properties and methods:

Name	Description
Add	Adds or replaces a skin object to the control.
Clear	Removes all skins in the control.
Remove	Removes a specific skin from the control.
RenderType	Specifies the way colored EBN objects are displayed on the component.

method Appearance.Add (ID as Long, Skin as Variant)

Adds or replaces a skin object to the control.

Type	Description
ID as Long	<p>A Long expression that indicates the index of the skin being added or replaced. The value must be between 1 and 126, so Appearance collection should holds no more than 126 elements.</p> <p>The Skin parameter of the Add method can a STRING as explained bellow, a BYTE[] / safe arrays of VT_I1 or VT_UI1 expression that indicates the content of the EBN file. You can use the BYTE[] / safe arrays of VT_I1 or VT_UI1 option when using the EBN file directly in the resources of the project. For instance, the VB6 provides the LoadResData to get the safe array o bytes for specified resource, while in VB/.NET or C# the internal class Resources provides definitions for all files being inserted. (ResourceManager.GetObject("ebn", resourceCulture))</p> <p>If the Skin parameter points to a string expression, it can be one of the following:</p> <ul style="list-style-type: none">• A path to the skin file (*.EBN). The ExButton component or ExEBN tool can be used to create, view or edit EBN files. For instance, "C:\Program Files\Exontrol\ExButton\Sample\EBN\MSOffice-Ribbon\msor_frameh.ebn"• A BASE64 encoded string that holds the skin file (*.EBN). Use the ExImages tool to build BASE 64 encoded strings of the skin file (*.EBN). The BASE64 encoded string starts with "gBFLBCJw..."• An Windows XP theme part, if the Skin parameter starts with "XP:". Use this option, to display any UI element of the Current Windows XP Theme, on any part of the control. In this case, the syntax of the Skin parameter is: "XP:ClassName Part State" where the ClassName defines the window/control class name in the Windows XP Theme, the Part indicates a long expression that defines the part, and the State indicates the state of the part to be shown. All known values for window/class, part and start are defined at

the end of this document. For instance the "XP:Header 1 2" indicates the part 1 of the Header class in the state 2, in the current Windows XP theme.

The following screen shots show a few Windows XP Theme Elements, running on Windows Vista and Windows 10:

Skin as Variant

- A copy of another skin with different coordinates (position, size), if the Skin parameter starts with "**CP:**". Use this option, to display the EBN, using different coordinates (position, size). By default, the EBN skin object is rendered on the part's client area. Using this option, you can display the same EBN, on a different position / size. In this case, the syntax of the Skin parameter is: "**CP:ID Left Top Right Bottom**"

where the ID is the identifier of the EBN to be used (it is a number that specifies the ID parameter of the Add method), Left, Top, Right and Bottom parameters/numbers specifies the relative position to the part's client area, where the EBN should be rendered. The Left, Top, Right and Bottom parameters are numbers (negative, zero or positive values, with no decimal), that can be followed by the D character which indicates the value according to the current DPI settings. For instance, "CP:1 -2 -2 2 2", uses the EBN with the identifier 1, and displays it on a 2-pixels wider rectangle no matter of the DPI settings, while "CP:1 -2D -2D 2D 2D" displays it on a 2-pixels wider rectangle if DPI settings is 100%, and on on a 3-pixels wider rectangle if DPI settings is 150%.

The following screen shot shows the same EBN being displayed, using different CP: options:

Return	Description
Boolean	A Boolean expression that indicates whether the new skin was added or replaced.

Use the Add method to add or replace skins to the control. The skin method, in it's simplest form, uses a single graphic file (*.ebn) assigned to a part of the control. By using a collection of objects laid over the graphic, it is possible to define which sections of the graphic will be used as borders, corners and other possible elements, fixing them to their proper position regardless of the size of the part. Use the [Remove](#) method to remove a specific skin from the control. Use the [Clear](#) method to remove all skins in the control. Use the [BeginUpdate](#) and [EndUpdate](#) methods to maintain performance while init the control. Use the [Refresh](#) method to refresh the control.

The identifier you choose for the skin is very important to be used in the background properties like explained bellow. Shortly, the color properties uses 4 bytes (DWORD, double WORD, and so on) to hold a RGB value. More than that, the first byte (most

significant byte in the color) is used only to specify system color. if the first bit in the byte is 1, the rest of bits indicates the index of the system color being used. So, we use the last 7 bits in the high significant byte of the color to indicates the identifier of the skin being used. So, since the 7 bits can cover 127 values, excluding 0, we have 126 possibilities to store an identifier in that byte. This way, a DWORD expression indicates the background color stored in RRGGBB format and the index of the skin (ID parameter) in the last 7 bits in the high significant byte of the color. For instance, the BackColor = BackColor Or &H2000000 indicates that we apply the skin with the index 2 using the old color, to the object that BackColor is applied.

Starting with **Windows XP**, the following table shows how the common controls are broken into parts and states:

method Appearance.Clear ()

Removes all skins in the control.

Type	Description
------	-------------

Use the Clear method to clear all skins from the control. Use the [Remove](#) method to remove a specific skin. If you need to remove the skin appearance from a part of the control you need to reset the last 7 bits in the high significant byte of the color being applied to the background's part.

method Appearance.Remove (ID as Long)

Removes a specific skin from the control.

Type	Description
ID as Long	A Long expression that indicates the index of the skin being removed.

Use the Remove method to remove a specific skin. The identifier of the skin being removed should be the same as when the skin was added using the [Add](#) method. Use the [Clear](#) method to clear all skins from the control. If you need to remove the skin appearance from a part of the control you need to reset the last 7 bits in the high significant byte of the color being applied to the background's part.

property Appearance.RenderType as Long

Specifies the way colored EBN objects are displayed on the component.

Type	Description
Long	A long expression that indicates how the EBN objects are shown in the control, like explained bellow.

By default, the RenderType property is 0, which indicates an A-color scheme. The RenderType property can be used to change the colors for the entire control, for parts of the controls that uses EBN objects. The RenderType property is not applied to the currently XP-theme if using.

The RenderType property is applied to all parts that displays an EBN object. The properties of color type may support the EBN object if the property's description includes "*A color expression that indicates the cell's background color. The last 7 bits in the high significant byte of the color to indicates the identifier of the skin being used. Use the [Add](#) method to add new skins to the control. If you need to remove the skin appearance from a part of the control you need to reset the last 7 bits in the high significant byte of the color being applied to the background's part.*" In other words, a property that supports EBN objects should be of format 0xIDRRGGBB, where the ID is the identifier of the EBN to be applied, while the BBGGRR is the (Red,Green,Blue, RGB-Color) color to be applied on the selected EBN. For instance, the 0x1000000 indicates displaying the EBN as it is, with no color applied, while the 0x1FF0000, applies the Blue color (RGB(0x0,0x0,0xFF), RGB(0,0,255) on the EBN with the identifier 1. You can use the [EBNColor](#) tool to visualize applying EBN colors.

Click here  to watch a movie on how you can change the colors to be applied on EBN objects.

In the following screen shot the following objects displays the current EBN with a different color:

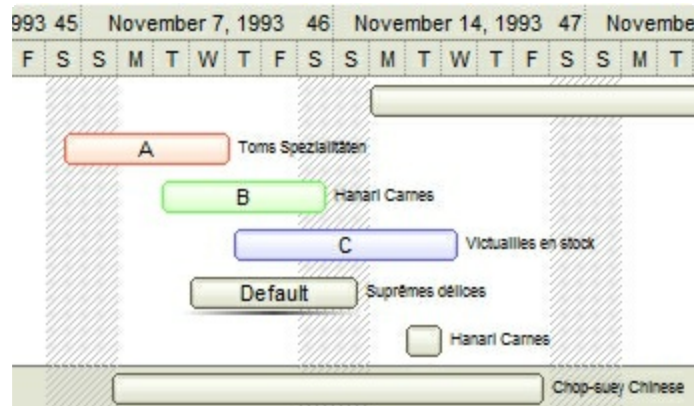

- "A" in Red (RGB(255,0,0) , for instance the bar's property exBarColor is 0x10000FF
- "B" in Green (RGB(0,255,0) , for instance the bar's property exBarColor is 0x100FF00
- "C" in Blue (RGB(0,0,255) , for instance the bar's property exBarColor is 0x1FF0000
- "Default", no color is specified, for instance the bar's property exBarColor is 0x1000000

The RenderType property could be one of the following:

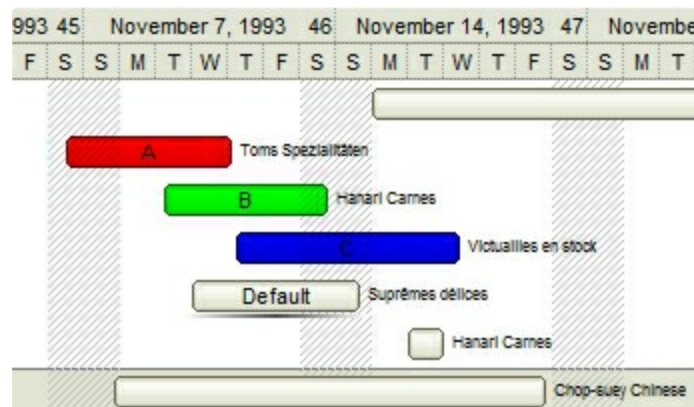

- **-3**, *no color is applied*. For instance, the BackColorHeader = &H1FF0000 is displayed as would be .BackColorHeader = &H1000000, so the 0xFF0000 color (Blue color) is ignored. You can use this option to allow the control displays the EBN colors or not.

- **-2, OR-color scheme.** The color to be applied on the part of the control is a OR bit combination between the original EBN color and the specified color. For instance, the BackColorHeader = &H1FF0000, applies the OR bit for the entire Blue channel, or in other words, it applies a less Blue to the part of the control. This option should be used with solid colors (RGB(255,0,0), RGB(0,255,0), RGB(0,0,255), RGB(255,255,0), RGB(255,0,255), RGB(0,255,255), RGB(127,0,0), RGB(0,127,0), ...)

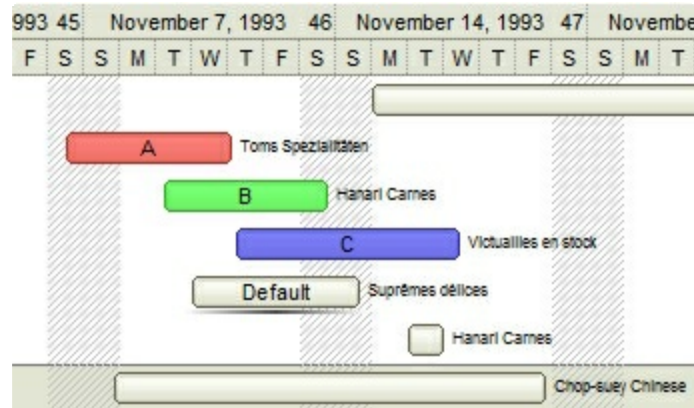

- **-1, AND-color scheme,** The color to be applied on the part of the control is an AND bit combination between the original EBN color and the specified color. For instance, the BackColorHeader = &H1FF0000, applies the AND bit for the entire Blue channel, or in other words, it applies a more Blue to the part of the control. This option should be used with solid colors (RGB(255,0,0), RGB(0,255,0), RGB(0,0,255), RGB(255,255,0), RGB(255,0,255), RGB(0,255,255), RGB(127,0,0), RGB(0,127,0), ...)

- **0, default,** the specified color is applied to the EBN. For instance, the

BackColorHeader = &H1FF0000, applies a Blue color to the object. This option could be used to specify any color for the part of the components, that support EBN objects, not only solid colors.

- **0xAABBGRR**, where the AA a value between 0 to 255, which indicates the transparency, and RR, GG, BB the red, green and blue values. This option applies the same color to all parts that displays EBN objects, whit ignoring any specified color in the color property. For instance, the RenderType on 0x4000FFFF, indicates a 25% Yellow on EBN objects. The 0x40, or 64 in decimal, is a 25 % from in a 256 interal, and the 0x00FFFF, indicates the Yellow (RGB(255,255,0)). The same could be if the RenderType is 0x40000000 + vbYellow, or &H40000000 + RGB(255, 255, 0), and so, the RenderType could be the 0xAA000000 + Color, where the Color is the RGB format of the color.

The following picture shows the control with the RenderType property on 0x4000FFFF (25% Yellow, 0x40 or 64 in decimal is 25% from 256):

The following picture shows the control with the RenderType property on 0x8000FFFF (50% Yellow, 0x80 or 128 in decimal is 50% from 256):

The following picture shows the control with the *RenderType* property on `0xC000FFFF` (75% Yellow, `0xC0` or 192 in decimal is 75% from 256):

The following picture shows the control with the *RenderType* property on `0xFF00FFFF` (100% Yellow, `0xFF` or 255 in decimal is 100% from 255):

Background object

The Background object holds pictures to be shown on the layer's background. The [Foreground](#) object holds the HTML captions to be shown on the layer's foreground. The [Background](#) property of the Layer access the layer's Background object. The layer's background can be visible or selectable. If not selectable, the user can not select it runtime, such as LayerFromPoint property ignores it. The Layer's background can display unlimited graphics of different sizes and positions.

The following screen shot shows a pictures on each layer's background:

The Background object supports the following properties and methods:

Name	Description
Color	Indicates the layer's Color object, so you can apply a solid color on the layer's background.
ExtraPicture	Indicates the layer's extra Picture object, so you can show any graphic on the layer's background.
Picture	Indicates the layer's Picture object, so you can show any graphic on the layer's background.
Selectable	Returns or sets a value that indicates whether all objects on the layer's background are selectable.
Visible	Specifies if the objects of the layer's background are shown or hidden.

property Background.Color as LColor

Indicates the layer's Color object, so you can apply a solid color on the layer's background.

Type	Description
LColor	A LColor object that holds the solid / EBN color to be applied on the layer's background.

By default, the layer's background is transparent. The [Picture](#) / [ExtraPicture](#) property should be used to place a picture on the layer's background. Use the [Value](#) property to specify a solid / EBN color to be applied on the layer's background.

The following properties can be used to move / resize the layer:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.

The following screen shot shows a layer with solid red color:

And if we decompose the layers we get:

The following samples show how you can apply a solid color to be display on left-half of the

layer after the first visible layer:

VBA (MS Access, Excell...)

```
With Gauge1
    .BeginUpdate
    .PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob

property Background.ExtraPicture (Key as Variant) as LPicture

Indicates the layer's extra Picture object, so you can show any graphic on the layer's background.

Type	Description
Key as Variant	Any VARIANT expression that identify the extra-picture to be shown on the layer's background.
LPicture	A LPicture object that specifies the extra-picture to be shown on the layer's background.

The Layer's background can display unlimited graphics of different sizes and positions. The [Picture](#) / ExtraPicture property adds a picture on the layer's background. Use the [Value](#) property to specify a solid / EBN color to be applied on the layer's background.

The following properties can be used to move / resize the picture on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

The following properties can be used to load / import (manually or automatically) pictures to the layer's background:

- [PicturesPath](#) property, specifies the path to load pictures from.
- [PicturesName](#) property, specifies the expression that defines the name of the file from the PicturesPath folder to be loaded.
- [Picture.Name](#) / [Picture.Value](#) property of the Background.Picture object, defines the name of the file to be loaded (relative, absolute, encoded or Picture object)

The [PicturesPath](#) / [PicturesName](#) properties can be used to automatically loads files from a specified folder to be displayed on the layer's background.

For instance,

```
PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob",
```

defines default folder to load pictures from.

`PicturesName = ""Layer` + str(value + 1) + `.png`"`, defines the name of the picture file to be loaded by the layer with the index / value. It defines the names as: Layer1.png for the layer with the index 0, Layer2.png for the layer with the index 1, Layer3.png for the layer with the index 2, and so on.

The [Picture.Name](#) / [Picture.Value](#) property of the Picture object loads a picture / graphics to be displayed on the layer's background.

The Name / Value property could be one of the following:

- A String expression indicates:
 - a name of a picture file in the PicturePath folder. For instance, Name = "Layer1.png", loads the Layer1.png file if found in the PicturePath folder.
 - a picture file including its absolute path. For instance, Name = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob\Layer1.png", loads the Layer1.png file from absolute path
 - a key of the HTML picture, previously loaded by the HTMLPicture method. For instance, Name = "pic1", loads the HTML picture with the key pic1, so the pic1 should be load previously with a HTMLPicture call like `HTMLPicture("pic1") = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob\Layer1.png"`
 - an encode BASE64 string of a picture file. The Exontrol's [ExImages](#) Tool encode/decode BASE64 strings from/to pictures. In this case, the string starts with "gB..", "gC.." and so on.
- A Picture object that indicates the picture to be displayed. For instance, Name = `LoadPicture("picture.jpg")`

property Background.Picture as LPicture

Indicates the layer's Picture object, so you can show any graphic on the layer's background.

Type	Description
LPicture	A LPicture object that specifies the picture to be shown on the layer's background.

The Layer's background can display unlimited graphics of different sizes and positions. The Picture / [ExtraPicture](#) property adds a picture on the layer's background. Use the [Value](#) property to specify a solid / EBN color to be applied on the layer's background.

The following properties can be used to move / resize the picture on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

The following properties can be used to load / import (manually or automatically) pictures to the layer's background:

- [PicturesPath](#) property, specifies the path to load pictures from.
- [PicturesName](#) property, specifies the expression that defines the name of the file from the PicturesPath folder to be loaded.
- [Picture.Name](#) / [Picture.Value](#) property of the Background.Picture object, defines the name of the file to be loaded (relative, absolute, encoded or Picture object)

The [PicturesPath](#) / [PicturesName](#) properties can be used to automatically loads files from a specified folder to be displayed on the layer's background.

For instance,

PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob",
defines default folder to load pictures from.

PicturesName = ""Layer` + str(value + 1) + `.png`", defines the name of the picture file

to be loaded by the layer with the index / value. It defines the names as: Layer1.png for the layer with the index 0, Layer2.png for the layer with the index 1, Layer3.png for the layer with the index 2, and so on.

The [Picture.Name](#) / [Picture.Value](#) property of the Picture object loads a picture / graphics to be displayed on the layer's background.

The Name / Value property could be one of the following:

- A String expression indicates:
 - a name of a picture file in the PicturePath folder. For instance, Name = "Layer1.png", loads the Layer1.png file if found in the PicturePath folder.
 - a picture file including its absolute path. For instance, Name = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob\Layer1.png", loads the Layer1.png file from absolute path
 - a key of the HTML picture, previously loaded by the HTMLPicture method. For instance, Name = "pic1", loads the HTML picture with the key pic1, so the pic1 should be load previously with a HTMLPicture call like HTMLPicture("pic1") = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob\Layer1.png"
 - an encode BASE64 string of a picture file. The Exontrol's [ExImages](#) Tool encode/decode BASE64 strings from/to pictures. In this case, the string starts with "gB..", "gC.." and so on.
- A Picture object that indicates the picture to be displayed. For instance, Name = LoadPicture("picture.jpg")

property Background.Selectable as Boolean

Returns or sets a value that indicates whether all objects on the layer's background are selectable.

Type	Description
Boolean	A Boolean expression that specifies whether the entire layer's background is selectable.

By default, the Selectable property is True, so the user can select the layer if the cursor hovers it. The Selectable property specifies whether the layer's background is selectable. You can use the [Grayscale](#) property to show the entire layer in gray scale (disable state). The [Visible](#) property specifies whether the layer's background is visible or hidden. The [Picture](#) / [ExtraPicture](#) property adds a picture on the layer's background. Use the [Value](#) property to specify a solid / EBN color to be applied on the layer's background.

The Selectable property of the Background object, affects all the pictures / colors being shown on the layer's background. In order to prevent selecting portions of the layer you can use any of the following properties:

- [Selectable](#) property of the LPicture object, returns or sets a value that indicates whether the picture is selectable.
- [Selectable](#) property of the LColor object, returns or sets a value that indicates whether the color is selectable.

property Background.Visible as Boolean

Specifies if the objects of the layer's background are shown or hidden.

Type	Description
Boolean	A Boolean expression that specifies whether the entire layer's background is visible or hidden.

By default, the Visible property is True, so any picture on the layer's background is visible. The Visible property specifies whether the layer's background is visible or hidden. The [Picture](#) / [ExtraPicture](#) property adds a picture on the layer's background. Use the [Value](#) property to specify a solid / EBN color to be applied on the layer's background. The [Selectable](#) property specifies whether the layer's background is selectable.

The Visible property of the Background object, affects all the pictures / colors being shown on the layer's background. In order to prevent showing portions of the layer you can use any of the following properties:

- [Visible](#) property of the LPicture object, specifies if the picture is shown or hidden on the layer's background.
- [Visible](#) property of the LColor object, specifies if the color is visible or hidden.

Clip object

The Clip object defines the clipping you can apply to any layer on the control. The Clipping support include intersection of any of rectangle, round rectangle, ellipse, pie, picture mask, polygon, and so on. The [Clip](#) property accesses the layer's Clip object.

Having the following layer:

By clipping, we can get something like follows:

and if we display the entire gauge here's what we get:

The Clip object supports the following properties and methods:

Name	Description
Ellipse	Gets access to the layer's ellipse clip object.
Picture	Gets access to the layer's picture clip object.
Pie	Gets access to the layer's pie clip object.
Polygon	Gets access to the layer's polygon clip object.
Rectangle	Gets access to the layer's rectangle clip object.
RoundRectangle	Gets access to the layer's round rectangle clip object.
Type	Specifies the type of the clipping the current layer supports.
Value	Indicates the object's value.

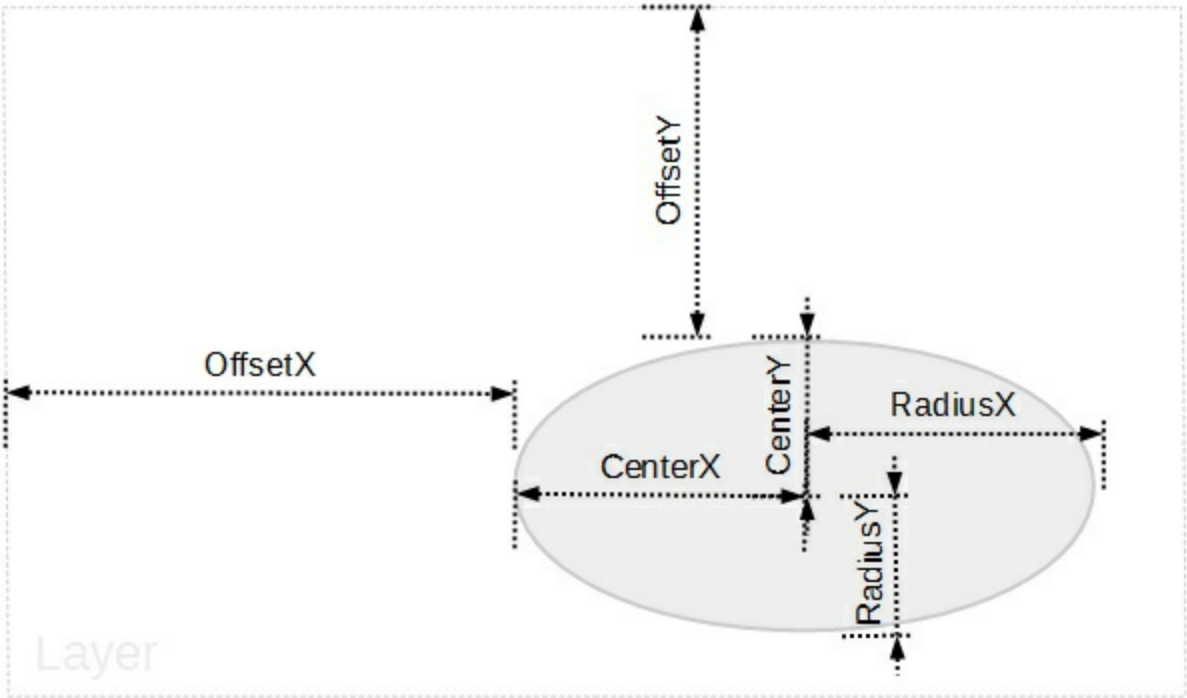

property Clip.Ellipse as ClipEllipse

Gets access to the layer's ellipse clip object.

Type	Description
ClipEllipse	A ClipEllipse object that holds information about elliptical clip region

The Ellipse property gets access to the layer's ellipse clip object.

The following screen shot shows properties of the clipping objects relative to the layer ([InverseClip](#) property is False, by default):

The following screen shot shows properties of the clipping objects relative to the layer ([InverseClip](#) property is True):

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

For instance, having the following gauge:

an elliptical clip region over the background layer shows as:

property Clip.Picture as ClipPicture

Gets access to the layer's picture clip object.

Type	Description
ClipPicture	A ClipPicture object that holds information about picture clip region

The Picture property gets access to the layer's picture clip object.

The following screen shot shows properties of the clipping objects relative to the layer ([InverseClip](#) property is False, by default):

The following screen shot shows properties of the clipping objects relative to the layer ([InverseClip](#) property is True):

To define a picture clip region over the layer you can use any of the following properties:

- [Name](#), Indicates the picture to be used as a mask/clip.
- [DisplayAs](#), Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.
- [AlphaFrom](#), Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
- [AlphaTo](#), Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

To specify the position / size of the picture clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

For instance, having the following gauge:

a picture clip region over the background layer shows as:

when the source picture is:

property Clip.Pie as ClipPie

Gets access to the layer's pie clip object.

Type	Description
ClipPie	A ClipPie object that holds information about pie clip region

The Pie property gets access to the layer's pie clip object.

The following screen shot shows properties of the clipping objects relative to the layer ([InverseClip](#) property is False, by default):

The following screen shot shows properties of the clipping objects relative to the layer ([InverseClip](#) property is True):

To define an pie clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.
- [StartAngle](#), Specifies the starting angle in degrees relative to the y-axis.
- [SweepAngle](#), Specifies the sweep angle in degrees relative to the starting angle.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

For instance, having the following gauge:

an pie clip region over the background layer shows as:

property Clip.Polygon as ClipPolygon

Gets access to the layer's polygon clip object.

Type	Description
ClipPolygon	A ClipPolygon object that holds information about polygonal clip region

The Polygon property gets access to the layer's polygon clip object.

The following screen shot shows properties of the clipping objects relative to the layer ([InverseClip](#) property is False, by default):

The following screen shot shows properties of the clipping objects relative to the layer ([InverseClip](#) property is True):

To define an polygonal clip region over the layer you can use any of the following properties:

- [Points](#), Indicates the number of points that defines the polygon.
- [X](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [Y](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

For instance, having the following gauge:

an polygonal clip region over the background layer shows as:

property Clip.Rectangle as ClipRectangle

Gets access to the layer's rectangle clip object.

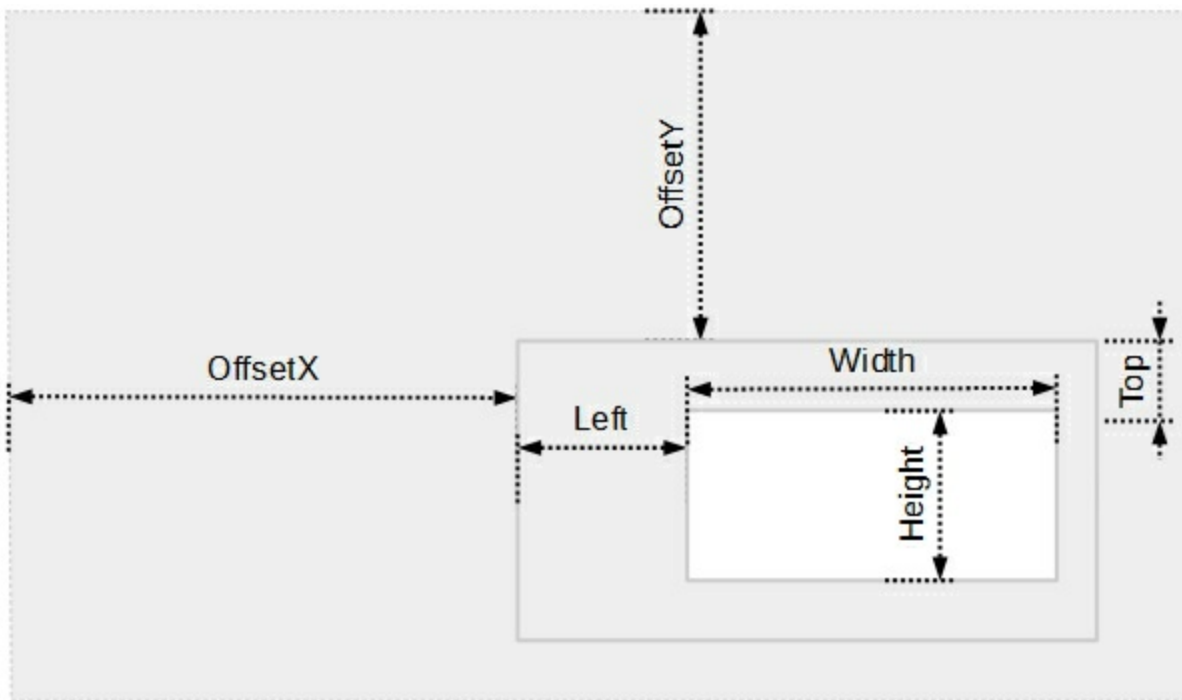

Type	Description
ClipRectangle	A ClipRectangle object that holds information about rectangular clip region

The Rectangle property gets access to the layer's rectangular clip object.

The following screen shot shows properties of the clipping objects relative to the layer ([InverseClip](#) property is False, by default):

The following screen shot shows properties of the clipping objects relative to the layer ([InverseClip](#) property is True):

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

For instance, having the following gauge:

a rectangular clip region over the background layer shows as:

property Clip.RoundRectangle as ClipRoundRectangle

Gets access to the layer's round rectangle clip object.

Type	Description
ClipRoundRectangle	A ClipRoundRectangle object that holds information about rectangular clip region

The RoundRectangle property gets access to the layer's round rectangular clip object.

The following screen shot shows properties of the clipping objects relative to the layer ([InverseClip](#) property is False, by default):

The following screen shot shows properties of the clipping objects relative to the layer ([InverseClip](#) property is True):

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.
- [RoundRadiusX](#), Specifies the x-radius value / expression of the round corner, relative to the layer.
- [RoundRadiusY](#), Specifies the y-radius value / expression of the round corner, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

For instance, having the following gauge:

a round rectangular clip region over the background layer shows as:

property Clip.Type as LayerClipTypeEnum

Specifies the type of the clipping the current layer supports.

Type	Description
LayerClipTypeEnum	A LayerClipTypeEnum expression that specifies the combination of clipping objects that currently is applied on the layer.

By default, the Type property is exLayerClipEmpty, which indicates that no clipping is applied to the layer. The Type property can be a combination of any flag of [LayerClipTypeEnum](#) type, which indicates intersection of the clipping objects will be applied on the layer. The Type property is automatically updated as soon as any property of any clipping object is invoked. In other words, if [RadiusY](#) property of the [ClipPie](#) object is called, the Type property includes automatically the exLayerClipPie. You can use the Type property to apply / prevent clipping to be applied on the specified layer. For instance, set the Type property on exLayerClipEmpty to prevent applying any clipping on the current layer. Changing the Type property at runtime, does not remove any clipping property of any clipping object.

property Clip.Value as Variant

Indicates the object's value.

Type	Description
Variant	A VARIANT expression to be used as a replacement of the value keyword in any property of Clip... objects.

By default, the Value property is empty. You can associate a value with a clipping object. For instance, let's say we define the value of a clipping rectangle as being its width. In other words, if we change the clip's Value property, the [Width](#) property of the [ClipRectangle](#) object is changed too, so the clipping rectangle will vary in its width. The same we can imagine the sweep angle or a pie or radius of a circle. The [Change](#) event notifies whether a layer is moved, rotated, so during this event we can call the clip's Value to update the clipping region on specified layer.

For instance, let's say that we have the following:

and we want to clip the "Clip" layer, as soon as the "Thumb" is rotated like follows:

so you need to do the following:

- specify the "Thumb" to be rotatable, using the [OnDrag](#) property, like `Layers.Item("Thumb").OnDrag = exDoRotate`. In case we need to specify a different initial position of the layer, we can call the [DefaultRotateAngle](#) property, to specify another angle by default.
- specify the clipping zone for "Clip" layer to be a pie, such as `Layers.Item("Clip").Clip.Pie.SweepAngle = "value"`, that specifies that the sweep angle of the clipping pie is controlled by the clip's Value property
- handle the [Change](#) event and call `Layers.Item("Clip").Clip.Value = Layers.Item("Thumb").RotateAngle`, which means that when any change occurs (the "Thumb" is rotated), change the Value of the Clip object of the "Clip" layer to be the rotate angle of the "Thumb" layer, so in other words as the clip's Value is associated with the sweep angle, change the sweep angle of the clipping pie to be the same as the rotation angle of the "Thumb" layer.

Now, let's say we want to remove the transparency on the "Clip" layer, so we need to add a new clipping object, this time of Picture object, with the same picture as:

- `Layers("Clip").Clip.Picture.Name = Layers("Clip").Background.Picture.Name`, which applies the clipping from the same picture, this time with no transparent pixels

so we get:

And if we hide a few intermediate layers we can get:

or if we add a new layer as a clone of others with a clipping pie we can get:

For instance, if you have:

- `Layers.Item("Clip").Clip.Value = 45`, you actually clip as a pie for a 45 degree the "Clip" layer.
- If using `Layers("Clip").Clip.Pie.SweepAngle = "2 * value"`, it indicates that the angle of the clipping region is twice the rotation angle of the thumb.
- If using `Layers("Clip").Clip.Pie.SweepAngle = "value / 2"`, it indicates that the angle of the clipping region is half of the rotation angle of the thumb.

Any of the following properties (or combination of them) can be used to do the clipping:

- [Ellipse](#), clips the layer as a ellipse / circle
- [Picture](#), clips the layer using a picture as a mask
- [Pie](#), clips the layer as a arc / pie
- [Polygon](#), clips the layer giving the points that define a polygon, triangle, rectangle, and so on
- [Rectangle](#), clips the layer giving a rectangle
- [RoundRectangle](#), clips the layer giving a round rectangle

ClipEllipse object

The ClipEllipse object holds information about an elliptical clip region.

For instance, having the following gauge:

an elliptical clip region over the background layer shows as:

The ClipEllipse supports the following properties and methods:

Name	Description
CenterX	Specifies the x-position / expression of the center of the clip, relative to the layer.
CenterY	Specifies the y-position / expression of the center of the clip, relative to the layer.
InverseClip	Indicates whether the current clip object is inverted.

[OffsetX](#)

Specifies the x-offset expression / value of the clip, relative to the layer.

[OffsetY](#)

Specifies the y-offset expression / value of the clip, relative to the layer.

[RadiusX](#)

Specifies the x-radius value / expression of the clip, relative to the layer.

[RadiusY](#)

Specifies the y-radius value / expression of the clip, relative to the layer.

property ClipEllipse.CenterX as String

Specifies the x-position / expression of the center of the clip, relative to the layer.

Type	Description
String	A String expression that defines the x-position / expression of the center of the clip, relative to the layer.

By default, the CenterX property is empty, which indicates the center of the layer The CenterX property is "width/2" (center of the layer), if the expression is missing or invalid.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- **CenterX**, Specifies the x-position / expression of the center of the clip, relative to the layer.
- [**CenterY**](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [**RadiusX**](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [**RadiusY**](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [**OffsetX**](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [**OffsetY**](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [**InverseClip**](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipEllipse.CenterY as String

Specifies the y-position / expression of the center of the clip, relative to the layer.

Type	Description
String	A String expression that defines the y-position / expression of the center of the clip, relative to the layer.

By default, the CenterY property is empty, which indicates the center of the layer The CenterY property is "height/2" (center of the layer), if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or right side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipEllipse.InverseClip as Boolean

Indicates whether the current clip object is inverted.

Type	Description
Boolean	A Boolean expression that indicates whether the current clip object is inverted.

By default, InverseClip property is False. The InverseClip property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

To define an elliptical clip region over the layer you can use any of the following properties:

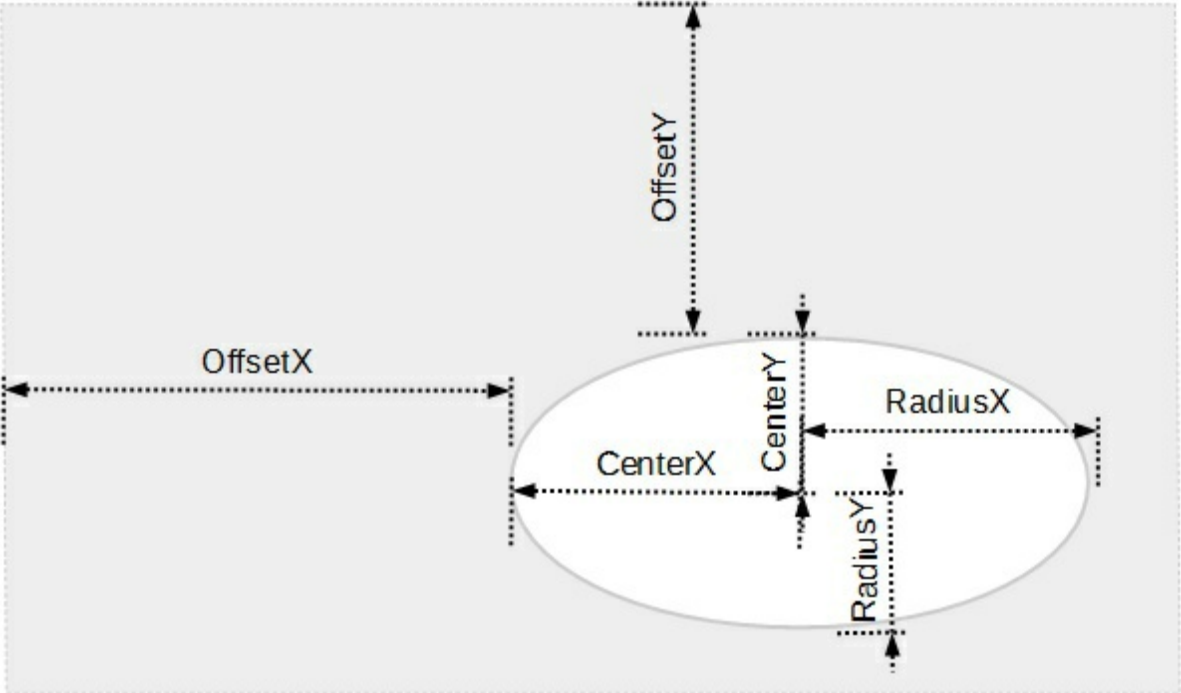

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The following screen shot shows properties of the clipping objects relative to the layer:

property ClipEllipse.OffsetX as String

Specifies the x-offset expression / value of the clip, relative to the layer.

Type	Description
String	A String expression that defines the x-offset expression / value of the clip, relative to the layer.

By default, the OffsetX property is empty, which indicates the value of 0 (left side of the layer). The OffsetX property is 0, if the expression is missing or invalid.

For instance:

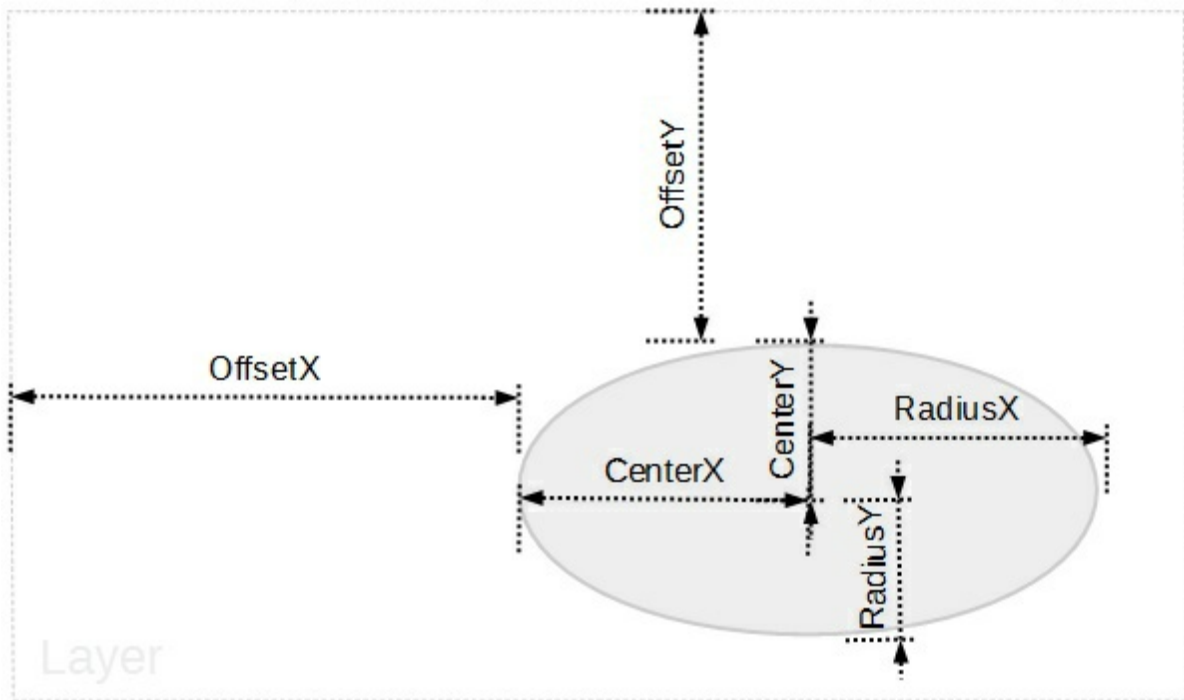

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipEllipse.OffsetY as String

Specifies the y-offset expression / value of the clip, relative to the layer.

Type	Description
String	A String expression that defines the y-offset expression / value of the clip, relative to the layer.

By default, the OffsetY property is empty, which indicates the value of 0 (top side of the layer). The OffsetY property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipEllipse.RadiusX as String

Specifies the x-radius value / expression of the clip, relative to the layer.

Type	Description
String	A String expression that defines the x-radius value / expression of the clip, relative to the layer.

By default, the RadiusX property is empty, which indicates the half of the layer's width. The RadiusX property is "width/2" (half of the layer's width), if the expression is missing or invalid.

For instance:

- "15", 15 pixels radius
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipEllipse.RadiusY as String

Specifies the y-radius value / expression of the clip, relative to the layer.

Type	Description
String	A String expression that defines the y-radius value / expression of the clip, relative to the layer.

By default, the RadiusY property is empty, which indicates the half of the layer's height. The RadiusY property is "height/2" (half of the layer's height), if the expression is missing or invalid.

For instance:

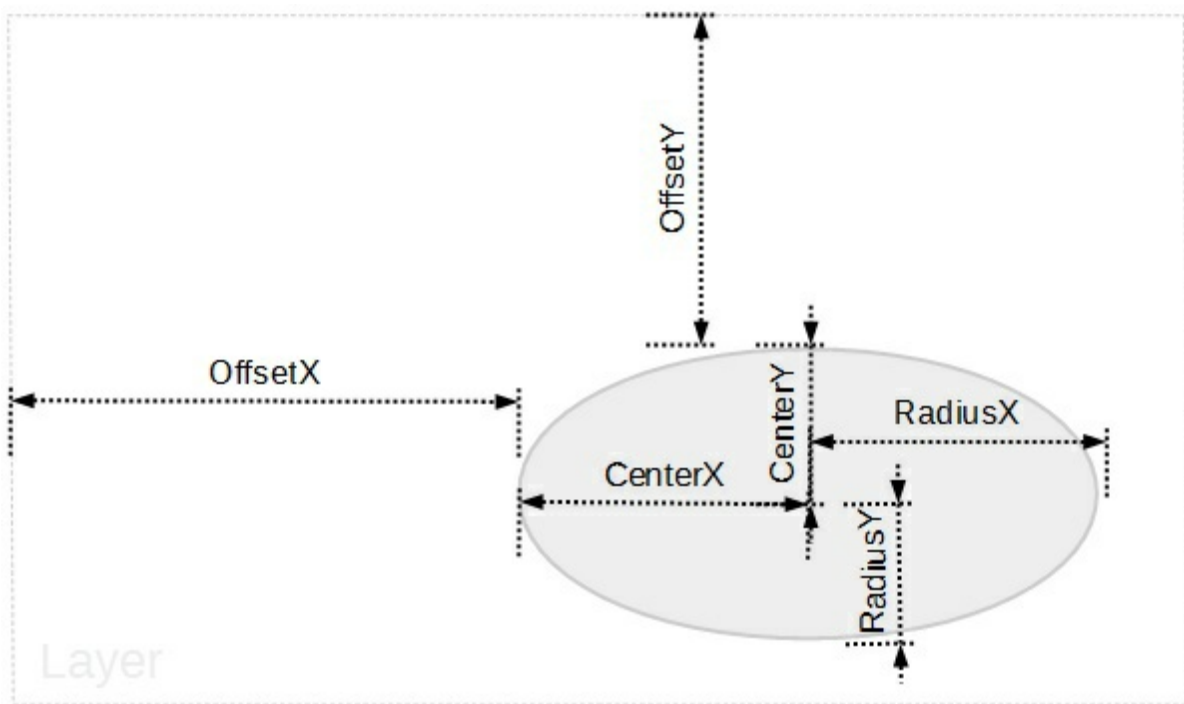

- "15", 15 pixels radius
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or right side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

ClipPicture object

The ClipPicture object holds information about an picture clip region.

For instance, having the following gauge:

a picture clip region over the background layer shows as:

when the source picture is:

The ClipPicture property supports the following properties and methods:

Name	Description
AlphaFrom	Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
AlphaTo	Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

[DisplayAs](#)

Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.

[Height](#)

Specifies the height value / expression of the clip, relative to the layer.

[InverseClip](#)

Indicates whether the current clip object is inverted.

[Left](#)

Specifies the left position / expression of the clip, relative to the layer.

[Name](#)

Indicates the picture to be used as a mask/clip.

[OffsetX](#)

Specifies the x-offset expression / value of the clip, relative to the layer.

[OffsetY](#)

Specifies the y-offset expression / value of the clip, relative to the layer.

[Top](#)

Specifies the top position / expression of the clip, relative to the layer.

[Width](#)

Specifies the width value / expression of the clip, relative to the layer.

property ClipPicture.AlphaFrom as String

Gets or sets a value that specifies the alpha-byte to start clipping the picture from.

Type	Description
String	A String expression that defines the alpha-byte to start clipping the picture from.

By default, the AlphaFrom and [AlphaTo](#) properties are empty. While AlphaFrom property is empty, missing or invalid, 0 is used instead. While AlphaTo property is empty, missing or invalid, 254 is used instead. In other words, any pixel in the picture with the transparency-byte on 255 defines the clipping region (by default, the opaque-pixels in the picture defines the clipping region.). Use the AlphaFrom / AlphaTo to include semi-transparent pixels in the clipping region. The picture being used as a clipping region must support transparency / alpha blending (picture's attribute includes the PICTURE_TRANSPARENT). For instance, you can use any PNG file with transparency. The [DisplayAs](#) property retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.

For instance, having a picture like follows:

if we apply this picture as a clipping, we get something like (includes pixels with alpha-blend byte on 255 only, opaque-pixels):

while if we change the AlphaTo field to 128 we can get something like (includes pixels with alpha-blend byte between 129 and 255, opaque plus semi-transparent pixels to 128):

or if we change the AlphaFrom and Alpha fields to 255, we can get something like (includes pixels with alpha-blend byte between 0 and 254, excludes the opaque pixels):

or if we change the AlphaFrom to 128, and Alpha field to 255, we can get something like (includes pixels with alpha-blend byte between 0 and 127, excludes the opaque pixels, and semi-transparent pixels to 128):

To define a picture clip region over the layer you can use any of the following properties:

- [Name](#), Indicates the picture to be used as a mask/clip.

- [DisplayAs](#), Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.
- [AlphaFrom](#), Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
- [AlphaTo](#), Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

To specify the position / size of the picture clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The following screen shot shows properties of the clipping objects relative to the layer:

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPicture.AlphaTo as String

Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

Type	Description
String	A String expression that specifies the alpha-byte to end clipping the picture to.

By default, the [AlphaFrom](#) and AlphaTo properties are empty. While AlphaFrom property is empty, missing or invalid, 0 is used instead. While AlphaTo property is empty, missing or invalid, 254 is used instead. In other words, any pixel in the picture with the transparency-byte on 255 defines the clipping region (by default, the opaque-pixels in the picture defines the clipping region.). Use the AlphaFrom / AlphaTo to include semi-transparent pixels in the clipping region. The picture being used as a clipping region must support transparency / alpha blending (picture's attribute includes the PICTURE_TRANSPARENT). For instance, you can use any PNG file with transparency. The [DisplayAs](#) property retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.

For instance, having a picture like follows:

if we apply this picture as a clipping, we get something like (includes pixels with alpha-blend byte on 255 only, opaque-pixels):

while if we change the AlphaTo field to 128 we can get something like (includes pixels with alpha-blend byte between 129 and 255, opaque plus semi-transparent pixels to 128):

or if we change the AlphaFrom and Alpha fields to 255, we can get something like (includes pixels with alpha-blend byte between 0 and 254, excludes the opaque pixels):

or if we change the AlphaFrom to 128, and Alpha field to 255, we can get something like (includes pixels with alpha-blend byte between 0 and 127, excludes the opaque pixels, and semi-transparent pixels to 128):

To define a picture clip region over the layer you can use any of the following properties:

- [Name](#), Indicates the picture to be used as a mask/clip.

- [DisplayAs](#), Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.
- [AlphaFrom](#), Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
- [AlphaTo](#), Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

To specify the position / size of the picture clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The following screen shot shows properties of the clipping objects relative to the layer:

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPicture.DisplayAs as PictureDisplayEnum

Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.

Type	Description
PictureDisplayEnum	A PictureDisplayEnum expression that indicates the way how the graphic is arranged on the mask/clip.

By default, the DisplayAs property is Stretch. The DisplayAs property retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip. The [Name](#) property loads a picture into the clip. The picture being used as a clipping region must support transparency / alpha blending (picture's attribute includes the PICTURE_TRANSPARENT). For instance, you can use any PNG file with transparency. By default, the opaque-pixels in the picture defines the clipping region. Use the [AlphaFrom](#) / [AlphaTo](#) to include semi-transparent pixels in the clipping region.

To define a picture clip region over the layer you can use any of the following properties:

- [Name](#), Indicates the picture to be used as a mask/clip.
- DisplayAs, Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.
- [AlphaFrom](#), Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
- [AlphaTo](#), Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

To specify the position / size of the picture clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- Height, Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The following screen shot shows properties of the clipping objects relative to the layer:

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPicture.Height as String

Specifies the height value / expression of the clip, relative to the layer.

Type	Description
String	A String value that specifies the height value / expression of the clip, relative to the layer.

By default, the Height property is empty, which indicates the height of the layer. The Height property is "height", if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define a picture clip region over the layer you can use any of the following properties:

- [Name](#), Indicates the picture to be used as a mask/clip.
- [DisplayAs](#), Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.
- [AlphaFrom](#), Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
- [AlphaTo](#), Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

To specify the position / size of the picture clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPicture.InverseClip as Boolean

Indicates whether the current clip object is inverted.

Type	Description
Boolean	A Boolean expression that indicates whether the current clip object is inverted.

By default, InverseClip property is False. The InverseClip property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

To define a picture clip region over the layer you can use any of the following properties:

- [Name](#), Indicates the picture to be used as a mask/clip.
- [DisplayAs](#), Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.
- [AlphaFrom](#), Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
- [AlphaTo](#), Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

To specify the position / size of the picture clip object you can use any of the following properties:

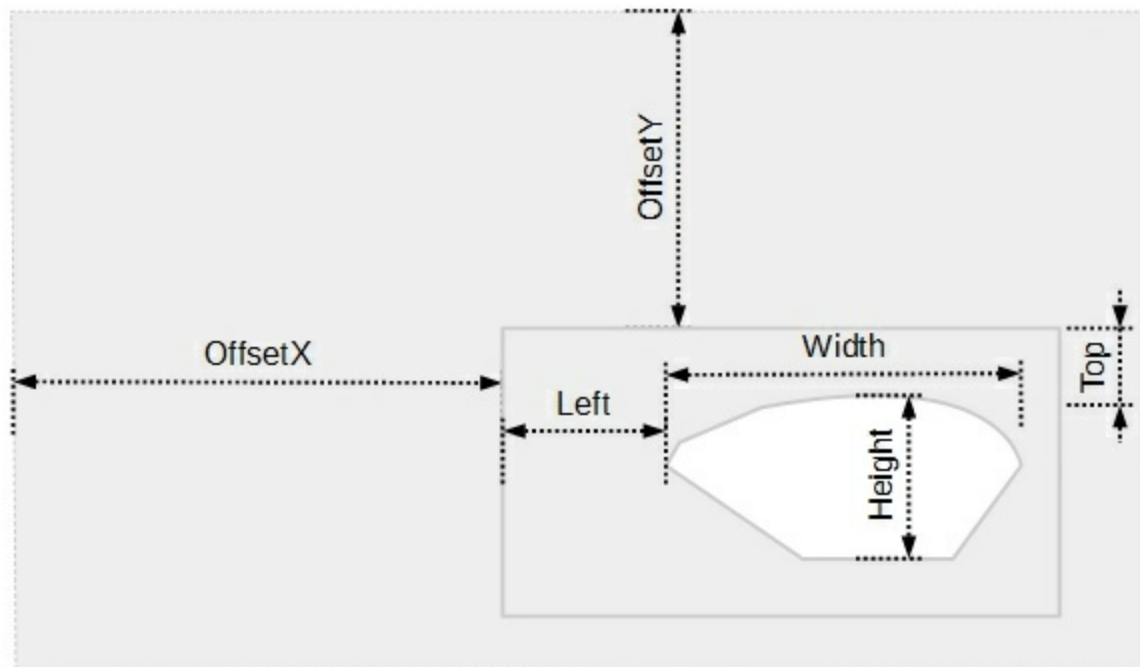

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- Height, Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The following screen shot shows properties of the clipping objects relative to the layer:

property ClipPicture.Left as String

Specifies the left position / expression of the clip, relative to the layer.

Type	Description
String	A String value that specifies the left position / expression of the clip, relative to the layer.

By default, the Left property is empty, which indicates the value of 0 (left side of the layer). The Left property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define a picture clip region over the layer you can use any of the following properties:

- [Name](#), Indicates the picture to be used as a mask/clip.
- [DisplayAs](#), Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.
- [AlphaFrom](#), Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
- [AlphaTo](#), Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

To specify the position / size of the picture clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPicture.Name as Variant

Indicates the picture to be used as a mask/clip.

Type	Description
Variant	<p>The Name property could be one of the following:</p> <ul style="list-style-type: none">• A String expression indicates:<ul style="list-style-type: none">◦ a name of a picture file in the PicturePath folder. For instance, Name = "Layer1.png", loads the Layer1.png file if found in the PicturesPath folder.◦ a picture file including its absolute path. For instance, Name = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\K loads the Layer1.png file from absolute path◦ a key of the HTML picture, previously loaded by the HTMLPicture method. For instance, Name = "pic1", loads the HTML picture with the key pic1, so the pic1 should be load previously with a HTMLPicture call like HTMLPicture("pic1") = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\K◦ an encode BASE64 string of a picture file. The Exontrol's ExImages Tool encode/decode BASE64 strings from/to pictures. In this case, the string starts with "gB..", "gC.." and so on.• A Picture object that indicates the picture to be displayed. For instance, Name = LoadPicture("picture.jpg")

By default, the Name property is empty, so no clipping is applied. The picture being used as a clipping region must support transparency / alpha blending (picture's attribute includes the PICTURE_TRANSPARENT). For instance, you can use any PNG file with transparency. By default, the opaque-pixels in the picture defines the clipping region. Use the [AlphaFrom](#) / [AlphaTo](#) to include semi-transparent pixels in the clipping region. The [DisplayAs](#) property retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.

To define a picture clip region over the layer you can use any of the following properties:

- Name, Indicates the picture to be used as a mask/clip.
- [DisplayAs](#), Retrieves or sets a value that indicates the way how the graphic is

arranged on the mask/clip.

- [AlphaFrom](#), Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
- [AlphaTo](#), Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

To specify the position / size of the picture clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The following screen shot shows properties of the clipping objects relative to the layer:

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPicture.OffsetX as String

Specifies the x-offset expression / value of the clip, relative to the layer.

Type	Description
String	A String expression that defines the x-offset expression / value of the clip, relative to the layer.

By default, the OffsetX property is empty, which indicates the value of 0 (left side of the layer). The OffsetX property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define a picture clip region over the layer you can use any of the following properties:

- [Name](#), Indicates the picture to be used as a mask/clip.
- [DisplayAs](#), Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.
- [AlphaFrom](#), Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
- [AlphaTo](#), Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

To specify the position / size of the picture clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPicture.OffsetY as String

Specifies the y-offset expression / value of the clip, relative to the layer.

Type	Description
String	A String expression that defines the y-offset expression / value of the clip, relative to the layer.

By default, the OffsetY property is empty, which indicates the value of 0 (top side of the layer). The OffsetY property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define a picture clip region over the layer you can use any of the following properties:

- [Name](#), Indicates the picture to be used as a mask/clip.
- [DisplayAs](#), Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.
- [AlphaFrom](#), Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
- [AlphaTo](#), Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

To specify the position / size of the picture clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPicture.Top as String

Specifies the top position / expression of the clip, relative to the layer.

Type	Description
String	A String value that specifies the top position / expression of the clip, relative to the layer.

By default, the Top property is empty, which indicates the value of 0 (top side of the layer). The Top property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define a picture clip region over the layer you can use any of the following properties:

- [Name](#), Indicates the picture to be used as a mask/clip.
- [DisplayAs](#), Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.
- [AlphaFrom](#), Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
- [AlphaTo](#), Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

To specify the position / size of the picture clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPicture.Width as String

Specifies the width value / expression of the clip, relative to the layer.

Type	Description
String	A String expression that specifies the width value / expression of the clip, relative to the layer.

By default, the Width property is empty, which indicates the width of the layer . The Width property is "width", if the expression is missing or invalid.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define a picture clip region over the layer you can use any of the following properties:

- [Name](#), Indicates the picture to be used as a mask/clip.
- [DisplayAs](#), Retrieves or sets a value that indicates the way how the graphic is arranged on the mask/clip.
- [AlphaFrom](#), Gets or sets a value that specifies the alpha-byte to start clipping the picture from.
- [AlphaTo](#), Gets or sets a value that specifies the alpha-byte to end clipping the picture to.

To specify the position / size of the picture clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

ClipPie object

The ClipPie object holds information about a pie clip region.

For instance, having the following gauge:

an pie clip region over the background layer shows as:

Name	Description
CenterX	Specifies the x-position / expression of the center of the clip, relative to the layer.
CenterY	Specifies the y-position / expression of the center of the clip, relative to the layer.
InverseClip	Indicates whether the current clip object is inverted.
	Specifies the x-offset expression / value of the clip,

OffsetX	relative to the layer.
OffsetY	Specifies the y-offset expression / value of the clip, relative to the layer.
RadiusX	Specifies the x-radius value / expression of the clip, relative to the layer.
RadiusY	Specifies the y-radius value / expression of the clip, relative to the layer.
StartAngle	Specifies the starting angle in degrees relative to the y-axis.
SweepAngle	Specifies the sweep angle in degrees relative to the starting angle.

property ClipPie.CenterX as String

Specifies the x-position / expression of the center of the clip, relative to the layer.

Type	Description
String	A String expression that defines the x-position / expression of the center of the clip, relative to the layer.

By default, the CenterX property is empty, which indicates the center of the layer. The CenterX property is "width/2" (center of the layer), if the expression is missing or invalid.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- **CenterX**, Specifies the x-position / expression of the center of the clip, relative to the layer.
- **CenterY**, Specifies the y-position / expression of the center of the clip, relative to the layer.
- **RadiusX**, Specifies the x-radius value / expression of the clip, relative to the layer.
- **RadiusY**, Specifies the y-radius value / expression of the clip, relative to the layer.
- **StartAngle**, Specifies the starting angle in degrees relative to the y-axis.
- **SweepAngle**, Specifies the sweep angle in degrees relative to the starting angle.

To move the clipping region you can use any of the following properties:

- **OffsetX**, Specifies the x-offset expression / value of the clip, relative to the layer.
- **OffsetY**, Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The **InverseClip** property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPie.CenterY as String

Specifies the y-position / expression of the center of the clip, relative to the layer.

Type	Description
String	A String expression that defines the y-position / expression of the center of the clip, relative to the layer.

By default, the CenterY property is empty, which indicates the center of the layer The CenterY property is "height/2" (center of the layer), if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or right side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.
- [StartAngle](#), Specifies the starting angle in degrees relative to the y-axis.
- [SweepAngle](#), Specifies the sweep angle in degrees relative to the starting angle.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPie.InverseClip as Boolean

Indicates whether the current clip object is inverted.

Type	Description
Boolean	A Boolean expression that indicates whether the current clip object is inverted.

By default, InverseClip property is False. The InverseClip property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

To define an elliptical clip region over the layer you can use any of the following properties:

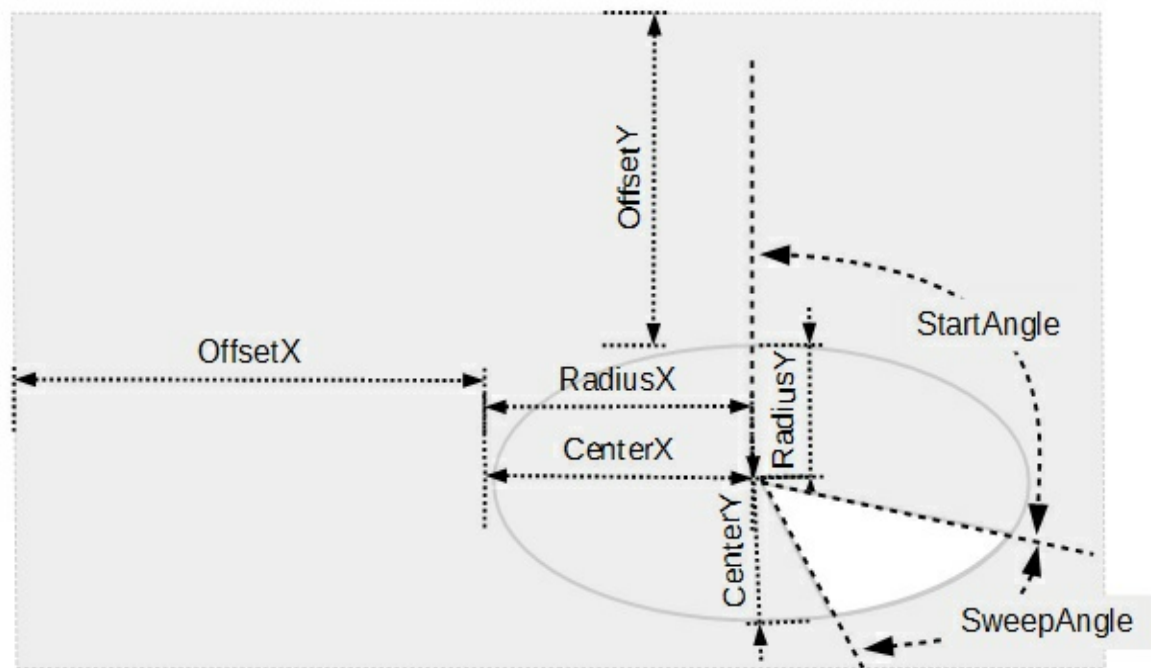

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.
- [StartAngle](#), Specifies the starting angle in degrees relative to the y-axis.
- [SweepAngle](#), Specifies the sweep angle in degrees relative to the starting angle.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The following screen shot shows properties of the clipping objects relative to the layer:

property ClipPie.OffsetX as String

Specifies the x-offset expression / value of the clip, relative to the layer.

Type	Description
String	A String expression that defines the x-offset expression / value of the clip, relative to the layer.

By default, the OffsetX property is empty, which indicates the value of 0 (left side of the layer). The OffsetX property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.
- [StartAngle](#), Specifies the starting angle in degrees relative to the y-axis.
- [SweepAngle](#), Specifies the sweep angle in degrees relative to the starting angle.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPie.OffsetY as String

Specifies the y-offset expression / value of the clip, relative to the layer.

Type	Description
String	A String expression that defines the y-offset expression / value of the clip, relative to the layer.

By default, the OffsetY property is empty, which indicates the value of 0 (top side of the layer). The OffsetY property is 0, if the expression is missing or invalid.

For instance:

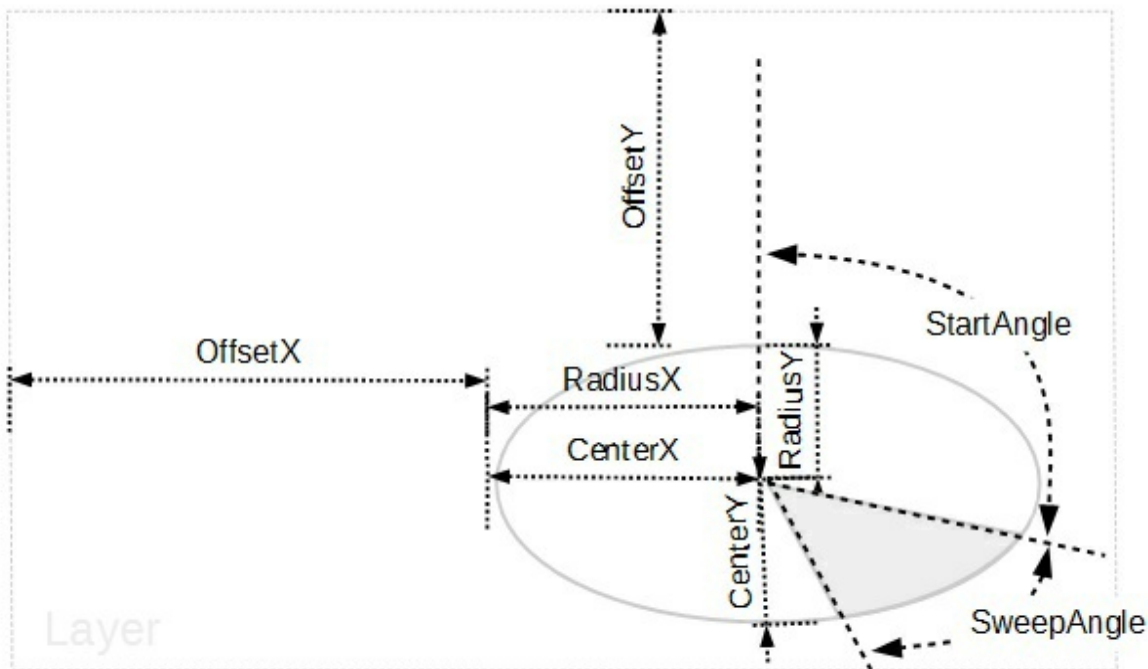

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.
- [StartAngle](#), Specifies the starting angle in degrees relative to the y-axis.
- [SweepAngle](#), Specifies the sweep angle in degrees relative to the starting angle.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPie.RadiusX as String

Specifies the x-radius value / expression of the clip, relative to the layer.

Type	Description
String	A String expression that defines the x-radius value / expression of the clip, relative to the layer.

By default, the RadiusX property is empty, which indicates the half of the layer's width. The RadiusX property is "width/2" (half of the layer's width), if the expression is missing or invalid.

For instance:

- "15", 15 pixels radius
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.
- [StartAngle](#), Specifies the starting angle in degrees relative to the y-axis.
- [SweepAngle](#), Specifies the sweep angle in degrees relative to the starting angle.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPie.RadiusY as String

Specifies the y-radius value / expression of the clip, relative to the layer.

Type	Description
String	A String expression that defines the y-radius value / expression of the clip, relative to the layer.

By default, the RadiusY property is empty, which indicates the half of the layer's height. The RadiusY property is "height/2" (half of the layer's height), if the expression is missing or invalid.

For instance:

- "15", 15 pixels radius
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or right side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.
- [StartAngle](#), Specifies the starting angle in degrees relative to the y-axis.
- [SweepAngle](#), Specifies the sweep angle in degrees relative to the starting angle.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPie.StartAngle as String

Specifies the starting angle in degrees relative to the y-axis.

Type	Description
String	A String expression that defines the starting angle in degrees relative to the y-axis.

By default, the StartAngle property is empty, which indicates 0 degree. The StartAngle property is 0 degree, if empty, missing or invalid.

For instance:

- "-45", 45 degree anti-clockwise
- "90", 90 degree clockwise
- "value" specifies that the angle is equal with the clip's [Value](#) property
- "value / 100 * 360" results the percent [Value](#) from 360 degree

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.
- [StartAngle](#), Specifies the starting angle in degrees relative to the y-axis.
- [SweepAngle](#), Specifies the sweep angle in degrees relative to the starting angle.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPie.SweepAngle as String

Specifies the sweep angle in degrees relative to the starting angle.

Type	Description
String	A String expression that defines the sweep angle in degrees relative to the starting angle.

By default, the SweepAngle property is empty, which indicates 0 degree. The SweepAngle property is 0 degree, if empty, missing or invalid.

For instance:

- "-45", 45 degree anti-clockwise
- "90", 90 degree clockwise
- "value" specifies that the angle is equal with the clip's [Value](#) property
- "value / 100 * 360" results the percent [Value](#) from 360 degree

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an elliptical clip region over the layer you can use any of the following properties:

- [CenterX](#), Specifies the x-position / expression of the center of the clip, relative to the layer.
- [CenterY](#), Specifies the y-position / expression of the center of the clip, relative to the layer.
- [RadiusX](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [RadiusY](#), Specifies the y-radius value / expression of the clip, relative to the layer.
- [StartAngle](#), Specifies the starting angle in degrees relative to the y-axis.
- [SweepAngle](#), Specifies the sweep angle in degrees relative to the starting angle.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

ClipPolygon object

The ClipPolygon object holds information about polygonal clip region.

For instance, having the following gauge:

an polygonal clip region over the background layer shows as:

The ClipPolygon object supports the following properties and methods:

Name	Description
InverseClip	Indicates whether the current clip object is inverted.
	Specifies the x-offset expression / value of the clip,

[OffsetX](#)

relative to the layer.

[OffsetY](#)

Specifies the y-offset expression / value of the clip, relative to the layer.

[Points](#)

Indicates the number of points that defines the polygon.

[X](#)

Specifies the x-position expression / value of the point, relative to the layer.

[Y](#)

Specifies the y-position expression / value of the point, relative to the layer.

property ClipPolygon.InverseClip as Boolean

Indicates whether the current clip object is inverted.

Type	Description
Boolean	A Boolean expression that indicates whether the current clip object is inverted.

By default, InverseClip property is False. The InverseClip property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

To define an polygonal clip region over the layer you can use any of the following properties:

- [Points](#), Indicates the number of points that defines the polygon.
- [X](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [Y](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The following screen shot shows properties of the clipping objects relative to the layer:

property ClipPolygon.OffsetX as String

Specifies the x-offset expression / value of the clip, relative to the layer.

Type	Description
String	A String expression that defines the x-offset expression / value of the clip, relative to the layer.

By default, the OffsetX property is empty, which indicates the value of 0 (left side of the layer). The OffsetX property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an polygonal clip region over the layer you can use any of the following properties:

- [Points](#), Indicates the number of points that defines the polygon.
- [X](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [Y](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPolygon.OffsetY as String

Specifies the y-offset expression / value of the clip, relative to the layer.

Type	Description
String	A String expression that defines the y-offset expression / value of the clip, relative to the layer.

By default, the OffsetY property is empty, which indicates the value of 0 (top side of the layer). The OffsetY property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an polygonal clip region over the layer you can use any of the following properties:

- [Points](#), Indicates the number of points that defines the polygon.
- [X](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [Y](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPolygon.Points as Long

Indicates the number of points that defines the polygon.

Type	Description
Long	A Long expression that defines the number of points within the polygon. The number of points must be greater or equal with 3.

By default, the Points property is 0. The Points property indicates the number of points that defines the polygon. The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

The following screen shot shows properties of the clipping objects relative to the layer:

To define an polygonal clip region over the layer you can use any of the following properties:

- Points, Indicates the number of points that defines the polygon.
- [X](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- Y, Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

property ClipPolygon.X(Index as Long) as String

Specifies the x-position expression / value of the point, relative to the layer.

Type	Description
Index as Long	A Long expression that specifies the index of the point, whose x-coordinate is accessed. The Index parameter is zero-based, so it can be 0, 1, 2, ... Points - 1
String	A String value that specifies the x-position expression / value of the point, relative to the layer.

By default, the X property is empty, which indicates the value of 0 (left side of the layer). The X property is 0, if the expression is empty, missing or invalid. The [Points](#) property indicates the number of points that defines the polygon.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an polygonal clip region over the layer you can use any of the following properties:

- [Points](#), Indicates the number of points that defines the polygon.
- [X](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [Y](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipPolygon.Y(Index as Long) as String

Specifies the y-position expression / value of the point, relative to the layer.

Type	Description
Index as Long	A Long expression that specifies the index of the point, whose x-coordinate is accessed. The Index parameter is zero-based, so it can be 0, 1, 2, ... Points - 1
String	A String value that specifies the y-position expression / value of the point, relative to the layer.

By default, the Y property is empty, which indicates the value of 0 (top side of the layer). The Y property is 0, if the expression is empty, missing or invalid. The [Points](#) property indicates the number of points that defines the polygon.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define an polygonal clip region over the layer you can use any of the following properties:

- [Points](#), Indicates the number of points that defines the polygon.
- [X](#), Specifies the x-radius value / expression of the clip, relative to the layer.
- [Y](#), Specifies the y-radius value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

ClipRectangle object

The ClipRectangle object holds information about an rectangular clip region.

For instance, having the following gauge:

a rectangular clip region over the background layer shows as:

The ClipRectangle property supports the following properties and methods:

Name	Description
Height	Specifies the height value / expression of the clip, relative to the layer.
InverseClip	Indicates whether the current clip object is inverted.
Left	Specifies the left position / expression of the clip, relative to the layer.
OffsetX	Specifies the x-offset expression / value of the clip,

relative to the layer.

[OffsetY](#)

Specifies the y-offset expression / value of the clip, relative to the layer.

[Top](#)

Specifies the top position / expression of the clip, relative to the layer.

[Width](#)

Specifies the width value / expression of the clip, relative to the layer.

property ClipRectangle.Height as String

Specifies the height value / expression of the clip, relative to the layer.

Type	Description
String	A String value that specifies the height value / expression of the clip, relative to the layer.

By default, the Height property is empty, which indicates the height of the layer. The Height property is "height", if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipRectangle.InverseClip as Boolean

Indicates whether the current clip object is inverted.

Type	Description
Boolean	A Boolean expression that indicates whether the current clip object is inverted.

By default, InverseClip property is False. The InverseClip property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

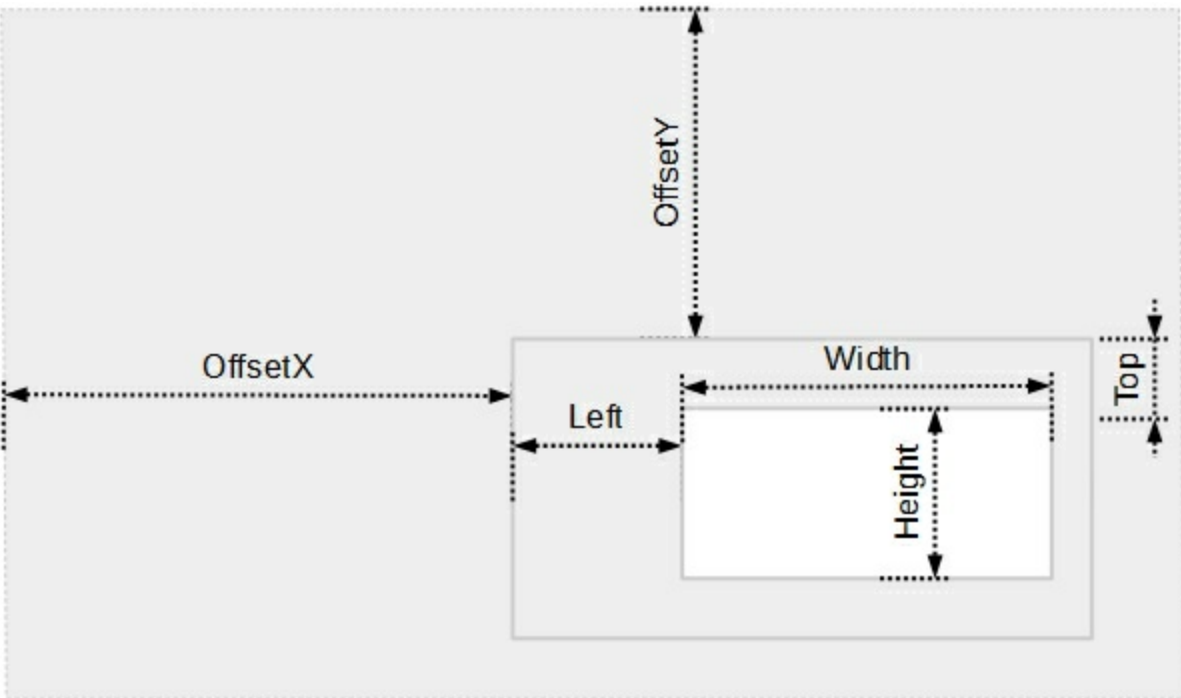

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- Height, Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The following screen shot shows properties of the clipping objects relative to the layer:

property ClipRectangle.Left as String

Specifies the left position / expression of the clip, relative to the layer.

Type	Description
String	A String value that specifies the left position / expression of the clip, relative to the layer.

By default, the Left property is empty, which indicates the value of 0 (left side of the layer). The Left property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- **Left**, Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipRectangle.OffsetX as String

Specifies the x-offset expression / value of the clip, relative to the layer.

Type	Description
String	A String expression that defines the x-offset expression / value of the clip, relative to the layer.

By default, the OffsetX property is empty, which indicates the value of 0 (left side of the layer). The OffsetX property is 0, if the expression is missing or invalid.

For instance:

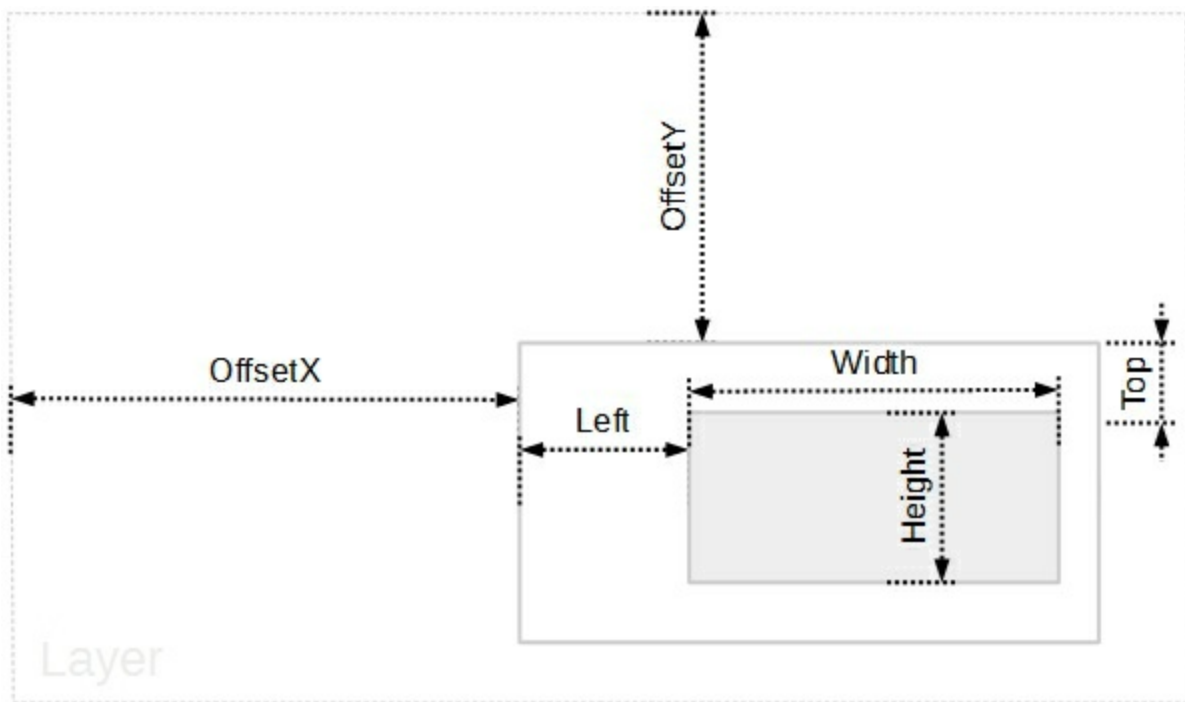

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipRectangle.OffsetY as String

Specifies the y-offset expression / value of the clip, relative to the layer.

Type	Description
String	A String expression that defines the y-offset expression / value of the clip, relative to the layer.

By default, the OffsetY property is empty, which indicates the value of 0 (top side of the layer). The OffsetY property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipRectangle.Top as String

Specifies the top position / expression of the clip, relative to the layer.

Type	Description
String	A String value that specifies the top position / expression of the clip, relative to the layer.

By default, the Top property is empty, which indicates the value of 0 (top side of the layer). The Top property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipRectangle.Width as String

Specifies the width value / expression of the clip, relative to the layer.

Type	Description
String	A String expression that specifies the width value / expression of the clip, relative to the layer.

By default, the Width property is empty, which indicates the width of the layer . The Width property is "width", if the expression is missing or invalid.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

ClipRoundRectangle object

The ClipRoundRectangle object holds information about an rectangular clip region.

For instance, having the following gauge:

a round rectangular clip region over the background layer shows as:

The ClipRoundRectangle property supports the following properties and methods:

Name	Description
Height	Specifies the height value / expression of the clip, relative to the layer.
InverseClip	Indicates whether the current clip object is inverted.
Left	Specifies the left position / expression of the clip, relative to the layer.
OffsetX	Specifies the x-offset expression / value of the clip, relative to the layer.

[OffsetY](#)

Specifies the y-offset expression / value of the clip, relative to the layer.

[RoundRadiusX](#)

Specifies the x-radius value / expression of the round corner, relative to the layer.

[RoundRadiusY](#)

Specifies the y-radius value / expression of the round corner, relative to the layer.

[Top](#)

Specifies the top position / expression of the clip, relative to the layer.

[Width](#)

Specifies the width value / expression of the clip, relative to the layer.

property ClipRoundRectangle.Height as String

Specifies the height value / expression of the clip, relative to the layer.

Type	Description
String	A String value that specifies the height value / expression of the clip, relative to the layer.

By default, the Height property is empty, which indicates the height of the layer. The Height property is "height", if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- Height, Specifies the height value / expression of the clip, relative to the layer.
- [RoundRadiusX](#), Specifies the x-radius value / expression of the round corner, relative to the layer.
- [RoundRadiusY](#), Specifies the y-radius value / expression of the round corner, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipRoundRectangle.InverseClip as Boolean

Indicates whether the current clip object is inverted.

Type	Description
Boolean	A Boolean expression that indicates whether the current clip object is inverted.

By default, InverseClip property is False. The InverseClip property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.
- [RoundRadiusX](#), Specifies the x-radius value / expression of the round corner, relative to the layer.
- [RoundRadiusY](#), Specifies the y-radius value / expression of the round corner, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The following screen shot shows properties of the clipping objects relative to the layer:

property ClipRoundRectangle.Left as String

Specifies the left position / expression of the clip, relative to the layer.

Type	Description
String	A String value that specifies the left position / expression of the clip, relative to the layer.

By default, the Left property is empty, which indicates the value of 0 (left side of the layer). The Left property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- **Left**, Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.
- [RoundRadiusX](#), Specifies the x-radius value / expression of the round corner, relative to the layer.
- [RoundRadiusY](#), Specifies the y-radius value / expression of the round corner, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipRoundRectangle.OffsetX as String

Specifies the x-offset expression / value of the clip, relative to the layer.

Type	Description
String	A String expression that defines the x-offset expression / value of the clip, relative to the layer.

By default, the OffsetX property is empty, which indicates the value of 0 (left side of the layer). The OffsetX property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.
- [RoundRadiusX](#), Specifies the x-radius value / expression of the round corner, relative to the layer.
- [RoundRadiusY](#), Specifies the y-radius value / expression of the round corner, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipRoundRectangle.OffsetY as String

Specifies the y-offset expression / value of the clip, relative to the layer.

Type	Description
String	A String expression that defines the y-offset expression / value of the clip, relative to the layer.

By default, the OffsetY property is empty, which indicates the value of 0 (top side of the layer). The OffsetY property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.
- [RoundRadiusX](#), Specifies the x-radius value / expression of the round corner, relative to the layer.
- [RoundRadiusY](#), Specifies the y-radius value / expression of the round corner, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipRoundRectangle.RoundRadiusX as String

Specifies the x-radius value / expression of the round corner, relative to the layer.

Type	Description
String	A String expression that defines the x-radius value / expression of the round corner, relative to the layer.

By default, the RoundRadiusX property is empty, which indicates 0 (no round corner). The Round RadiusX property is 0 (no round corner), if the expression is empty, missing or invalid.

For instance:

- "15", 15 pixels radius
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.
- [RoundRadiusX](#), Specifies the x-radius value / expression of the round corner, relative to the layer.
- [RoundRadiusY](#), Specifies the y-radius value / expression of the round corner, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipRoundRectangle.RoundRadiusY as String

Specifies the y-radius value / expression of the round corner, relative to the layer.

Type	Description
String	A String expression that defines the y-radius value / expression of the round corner, relative to the layer.

By default, the RoundRadiusY property is empty, which indicates 0 (no round corner). The RoundRadiusY property is 0 (no round corner), if the expression is empty, missing or invalid.

For instance:

- "15", 15 pixels radius
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or right side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.
- [RoundRadiusX](#), Specifies the x-radius value / expression of the round corner, relative to the layer.
- [RoundRadiusY](#), Specifies the y-radius value / expression of the round corner, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipRoundRectangle.Top as String

Specifies the top position / expression of the clip, relative to the layer.

Type	Description
String	A String value that specifies the top position / expression of the clip, relative to the layer.

By default, the Top property is empty, which indicates the value of 0 (top side of the layer). The Top property is 0, if the expression is missing or invalid.

For instance:

- "-15", 15 pixels up to the top side of the layer
- "height / 2" indicates the half of the layer's height or the y-center of the layer
- "height", indicates the height of the layer or bottom side of the layer
- "value / 100 * height", indicates the [Value](#) percent of height of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * height" expression gets a quarter of the height of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.
- [RoundRadiusX](#), Specifies the x-radius value / expression of the round corner, relative to the layer.
- [RoundRadiusY](#), Specifies the y-radius value / expression of the round corner, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

property ClipRoundRectangle.Width as String

Specifies the width value / expression of the clip, relative to the layer.

Type	Description
String	A String expression that specifies the width value / expression of the clip, relative to the layer.

By default, the Width property is empty, which indicates the width of the layer . The Width property is "width", if the expression is missing or invalid.

For instance:

- "-15", 15 pixels to the left side of the layer
- "width / 2" indicates the half of the layer's width or the x-center of the layer
- "width", indicates the width of the layer or right side of the layer
- "value / 100 * width", indicates the [Value](#) percent of width of the layer, so if clip's [Value](#) percent is 25, the "value / 100 * width" expression gets a quarter of the width of the layer, or 50 gets half of it, and so on.

This property supports the following keywords:

- **value** keyword specifies the clip's value pointed by the clip's [Value](#) property
- **width** or **lwidth** keywords, indicates the width in pixels of the layer
- **height** or **lheight** keywords, indicates the height in pixels of the layer

Also, this property supports all constants, operators and functions defined [here](#).

The following screen shot shows properties of the clipping objects relative to the layer:

To define or specify the position / size of the rectangular clip object you can use any of the following properties:

- [Left](#), Specifies the left position / expression of the clip, relative to the layer.
- [Top](#), Specifies the top position / expression of the clip, relative to the layer.
- [Width](#), Specifies the width value / expression of the clip, relative to the layer.
- [Height](#), Specifies the height value / expression of the clip, relative to the layer.
- [RoundRadiusX](#), Specifies the x-radius value / expression of the round corner, relative to the layer.
- [RoundRadiusY](#), Specifies the y-radius value / expression of the round corner, relative to the layer.

To move the clipping region you can use any of the following properties:

- [OffsetX](#), Specifies the x-offset expression / value of the clip, relative to the layer.
- [OffsetY](#), Specifies the y-offset expression / value of the clip, relative to the layer.

If none of these properties are calling no clipping is applied to layer.

The [InverseClip](#) property inverses the current clipping region, so anything that was included in the clipping region will be excluded, and reverse.

DragInfo object

The DragInfo object holds information about dragging operation. Currently, the DragInfo object can be accessed through the drag events. Any layer on the control supports drag operations like moving, rotation, or combination of them, when the user clicks and drags a layer. The drag operation automatically starts when the user clicks a visible, selectable and draggable layer. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (draggable). The [Visible](#) property shows or hides a specific layer (visible). The [Selectable](#) property returns or sets a value that indicates whether the layer is selectable. The [Change](#) event occurs when the layer's value is changed.

The control fires the drag events in the following order:

- [DragStart](#) event, notifies that a layer begins to drag. You can use the DragStart event to cancel the dragging operation.
- [Drag](#) event, notifies that the layer is dragging. You can use the Drag event to perform other actions, on any layer during the dragging operation.
- [DragEnd](#) event notifies, the dragging the layer ends. You can use the DragEnd event to perform other actions, on any layer when dragging operation ends.

The following screen shot shows a few information (angle, offset, values, ...) you can get during dragging operation:

The DragInfo object supports the following properties and methods:

Name	Description
Button	Specifies the button that initiated the drag operation.
Clockwise	Indicates if the rotation is clockwise or anticlockwise.
CumulativeRotateAngle	Indicates the cumulative rotation angle.
CurrentX	Indicates the current x-position of the cursor, while dragging the layer.
CurrentY	Indicates the current y-position of the cursor, while dragging the layer.
Debug	Specifies debugging information to be shown while dragging the layers.
Delta	Returns the distance between clicking and current points.
DeltaAngle	Returns the rotation angle.
DeltaX	Returns the offset on the x-coordinate of the the current drag operation.
DeltaY	Returns the offset on the y-coordinate of the the current drag operation.
Layer	Specifies the layer being dragged.
RotateAngleValid	Validates the rotation angle of the layer, during dragging.
UserData	Indicates any extra data associated with the dragging data.
X	Indicates the x-position of the cursor, when the drag operation starts.
Y	Indicates the y-position of the cursor, when the drag operation starts.

property DragInfo.Button as Long

Specifies the button that initiated the drag operation.

Type	Description
Long	A Long expression that specifies the button that initiated the drag operation. 1 indicates the left mouse button, while 2 indicates the right mouse button.

The Button property indicates the button that initiated the drag operation. The Button property is read-only. The drag operation can start if clicking with left or right mouse button any visible / selectable / draggable layer in the control. For instance, you can disable dragging with the right mouse button by changing the Change parameter of the [DragStart](#) event, to True, if the Button property is 2. The drag operation ends when the user releases the mouse button, or the user presses the ESC key. The [DragEnd](#) event notifies that the dragging the layer ends.

property DragInfo.Clockwise as Boolean

Indicates if the rotation is clockwise or anticlockwise.

Type	Description
Boolean	A Boolean expression that specifies whether the rotation is clockwise or anticlockwise.

The Clockwise property indicates if the rotation is clockwise or anticlockwise. A clockwise (typically abbreviated as CW) motion is one that proceeds in the same direction as a clock's hands: from the top to the right, then down and then to the left, and back up to the top. The Clockwise property is updated once you start rotating the object. The [DeltaAngle](#) property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation. The [CumulativeRotateAngle](#) property specifies the cumulative rotation angle, during the dragging operation. The [RotateAngle](#) property specifies the current angle of the rotation of the specified layer. The [RotateAngleValid](#) property specifies an expression that validates the rotation angle of the layer, during dragging operation.

property DragInfo.CumulativeRotateAngle as Double

Indicates the cumulative rotation angle.

Type	Description
Double	A Double expression that specifies the cumulative rotation angle.

The CumulativeRotateAngle property specifies the cumulative rotation angle, during the dragging operation. The [DeltaAngle](#) property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation. The [RotateAngleValid](#) property specifies an expression that validates the rotation angle of the layer, during dragging operation. The [RotateAngle](#) property specifies the current angle of the rotation of the specified layer. The [Clockwise](#) property indicates if the rotation is clockwise or anticlockwise. A clockwise (typically abbreviated as CW) motion is one that proceeds in the same direction as a clock's hands: from the top to the right, then down and then to the left, and back up to the top.

property DragInfo.CurrentX as Long

Indicates the current x-position of the cursor, while dragging the layer.

Type	Description
Long	A Long expression that indicates the current x-position of the cursor, while dragging the layer.

The CurrentX / [CurrentY](#) property indicates the current (x,y)-position of the cursor, relative to the upper-left corner of the control, while dragging the layer. The [OffsetX](#) / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [OffsetXValid](#) / [OffsetYValid](#) property to validate the (x,y)-position of the layer. For instance, you can use the OffsetYValid property on "0", and so no vertical movement is allowed.

The following properties can be used during dragging to determine the horizontal / vertical offset:

- [X](#) property indicates the x-position of the cursor, when the drag operation starts.
- [Y](#) property indicates the y-position of the cursor, when the drag operation starts.
- CurrentX property indicates the current x-position of the cursor, while dragging the layer.
- [CurrentY](#) property indicates the current y-position of the cursor, while dragging the layer.
- [Delta](#) property, returns the distance between clicking and current points.
- [DeltaX](#) property returns the offset on the x-coordinate of the the current drag operation, equivalent with the value of CurrentX - X.
- [DeltaY](#) property returns the offset on the y-coordinate of the the current drag operation, equivalent with the value of CurrentY - Y.

The [DeltaAngle](#) property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation.

property DragInfo.CurrentY as Long

Indicates the current y-position of the cursor, while dragging the layer.

Type	Description
Long	A Long expression that indicates the current y-position of the cursor, while dragging the layer.

The [CurrentX](#) / CurrentY property indicates the current (x,y)-position of the cursor, relative to the upper-left corner of the control, while dragging the layer. The [OffsetX](#) / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [OffsetXValid](#) / [OffsetYValid](#) property to validate the (x,y)-position of the layer. For instance, you can use the OffsetXValid property on "0", and so no horizontal movement is allowed.

The following properties can be used during dragging to determine the horizontal / vertical offset:

- [X](#) property indicates the x-position of the cursor, when the drag operation starts.
- [Y](#) property indicates the y-position of the cursor, when the drag operation starts.
- [CurrentX](#) property indicates the current x-position of the cursor, while dragging the layer.
- CurrentY property indicates the current y-position of the cursor, while dragging the layer.
- [Delta](#) property, returns the distance between clicking and current points.
- [DeltaX](#) property returns the offset on the x-coordinate of the the current drag operation, equivalent with the value of CurrentX - X.
- [DeltaY](#) property returns the offset on the y-coordinate of the the current drag operation, equivalent with the value of CurrentY - Y.

The [DeltaAngle](#) property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation.

property DragInfo.Debug as DebugLayerDragEnum

Specifies debugging information to be shown while dragging the layers.

Type	Description
DebugLayerDragEnum	A DebugLayerDragEnum expression that specifies the information to be included when debugging the drag operation.

By default, the Debug property is exDebugLayerDragNothing, so no debug information is displayed during the drag operation. The Debug property specifies debugging information to be shown while dragging the layers. The Debug property should be called during the [DragStart](#) event, or whenever debugging information should be displayed. The debugging information includes offsets, angles, values, and so on. Use the [Debug](#) property of the Control to display layers in debug mode. During drag operation you can use the [RotateAngleValid](#) property to limit the rotation angle.

The following information shows all debug information while dragging the layer:

property DragInfo.Delta as Double

Returns the distance between clicking and current points.

Type	Description
Double	A Double expression that specifies the distance between (CurrentX,CurrentY) and (X,Y) points.

The Delta property, returns the distance between clicking and current points. The [CurrentX](#) / [CurrentY](#) property indicates the current (x,y)-position of the cursor, relative to the upper-left corner of the control, while dragging the layer. The [OffsetX](#) / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [OffsetXValid](#) / [OffsetYValid](#) property to validate the (x,y)-position of the layer. For instance, you can use the OffsetYValid property on "0", and so no vertical movement is allwed.

The following properties can be used during dragging to determine the horizontal / vertical offset:

- [X](#) property indicates the x-position of the cursor, when the drag operation starts.
- [Y](#) property indicates the y-position of the cursor, when the drag operation starts.
- [CurrentX](#) property indicates the current x-position of the cursor, while dragging the layer.
- [CurrentY](#) property indicates the current y-position of the cursor, while dragging the layer.
- Delta property, returns the distance between clicking and current points.
- [DeltaX](#) property returns the offset on the x-coordinate of the the current drag operation, equivalent with the value of CurrentX - X.
- [DeltaY](#) property returns the offset on the y-coordinate of the the current drag operation, equivalent with the value of CurrentY - Y.

The [DeltaAngle](#) property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation.

property DragInfo.DeltaAngle as Double

Returns the rotation angle.

Type	Description
Double	A double expression that specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation.

The DeltaAngle property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation. The Clockwise property indicates if the rotation is clockwise or anticlockwise. A clockwise (typically abbreviated as CW) motion is one that proceeds in the same direction as a clock's hands: from the top to the right, then down and then to the left, and back up to the top. The [RotateAngle](#) property specifies the current angle of the rotation of the specified layer. The [CumulativeRotateAngle](#) property specifies the cumulative rotation angle, during the dragging operation. The [RotateAngleValid](#) property specifies an expression that validates the rotation angle of the layer, during dragging operation. The [OffsetX](#) / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [OffsetXValid](#) / [OffsetYValid](#) property to validate the (x,y)-position of the layer. For instance, you can use the OffsetYValid property on "0", and so no vertical movement is allowed.

The following properties can be used during dragging to determine the horizontal / vertical offset:

- [X](#) property indicates the x-position of the cursor, when the drag operation starts.
- [Y](#) property indicates the y-position of the cursor, when the drag operation starts.
- [CurrentX](#) property indicates the current x-position of the cursor, while dragging the layer.
- [CurrentY](#) property indicates the current y-position of the cursor, while dragging the layer.
- [Delta](#) property, returns the distance between clicking and current points.
- [DeltaX](#) property returns the offset on the x-coordinate of the the current drag operation, equivalent with the value of CurrentX - X.
- [DeltaY](#) property returns the offset on the y-coordinate of the the current drag operation, equivalent with the value of CurrentY - Y.

property DragInfo.DeltaX as Long

Returns the offset on the x-coordinate of the the current drag operation.

Type	Description
Long	A Long expression that returns the offset on the x-coordinate of the the current drag operation.

The DeltaX / [DeltaY](#) property indicates the current (horizontal, vertical)-offset of the movement during dragging operation. The [OffsetX](#) / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [OffsetXValid](#) / [OffsetYValid](#) property to validate the (x,y)-position of the layer. For instance, you can use the OffsetYValid property on "0", and so no vertical movement is allowed.

The following properties can be used during dragging to determine the horizontal / vertical offset:

- [X](#) property indicates the x-position of the cursor, when the drag operation starts.
- [Y](#) property indicates the y-position of the cursor, when the drag operation starts.
- [CurrentX](#) property indicates the current x-position of the cursor, while dragging the layer.
- [CurrentY](#) property indicates the current y-position of the cursor, while dragging the layer.
- [Delta](#) property, returns the distance between clicking and current points.
- DeltaX property returns the offset on the x-coordinate of the the current drag operation, equivalent with the value of CurrentX - X.
- [DeltaY](#) property returns the offset on the y-coordinate of the the current drag operation, equivalent with the value of CurrentY - Y.

The [DeltaAngle](#) property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation.

property DragInfo.DeltaY as Long

Returns the offset on the y-coordinate of the the current drag operation.

Type	Description
Long	A Long expression that returns the offset on the y-coordinate of the the current drag operation.

The [DeltaX](#) / DeltaY property indicates the current (horizontal, vertical)-offset of the movement during dragging operation. The [OffsetX](#) / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [OffsetXValid](#) / [OffsetYValid](#) property to validate the (x,y)-position of the layer. For instance, you can use the OffsetXValid property on "0", and so no horizontal movement is allowed.

The following properties can be used during dragging to determine the horizontal / vertical offset:

- [X](#) property indicates the x-position of the cursor, when the drag operation starts.
- [Y](#) property indicates the y-position of the cursor, when the drag operation starts.
- [CurrentX](#) property indicates the current x-position of the cursor, while dragging the layer.
- [CurrentY](#) property indicates the current y-position of the cursor, while dragging the layer.
- [Delta](#) property, returns the distance between clicking and current points.
- [DeltaX](#) property returns the offset on the x-coordinate of the the current drag operation, equivalent with the value of CurrentX - X.
- DeltaY property returns the offset on the y-coordinate of the the current drag operation, equivalent with the value of CurrentY - Y.

The [DeltaAngle](#) property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation.

property DragInfo.Layer as Long

Specifies the layer being dragged.

Type	Description
Long	A Long expression that specifies the index of the layer being dragged.

By default, the Layer property indicates the layer being clicked when the drag operation begins. You can change the Layer property to perform the drag operation to any other layer. In order to do that, you need to change the layer's OnDrag property. The [OnDrag](#) property indicates the action to be performed when the user drags the layer. You can use the [LayerFromPoint\(-1,-1\)](#) property to get the layer from the cursor.

The following samples show how you can rotate the layer with the index 9, by clicking anywhere on the control:

VBA (MS Access, Excell...)

```
' DragStart event - Occurs once the user starts dragging a layer.
Private Sub Gauge1_DragStart(ByVal DragInfo As Object,Cancel As Boolean)
    ' DragInfo.Layer = 9
    ' Layers(DragInfo.Layer).OnDrag = 2
End Sub

With Gauge1
    .PicturesPath = "C:\Program
Files\Exontrol\ExGauge\Sample\Design\Circular\Knob"
    .PicturesName = "`Layer` + int(value + 1) + `.png`"
    .Layers.Count = 11
End With
```

VB6

```
' DragStart event - Occurs once the user starts dragging a layer.
Private Sub Gauge1_DragStart(ByVal DragInfo As EXGAUGELibCtl.IDragInfo,Cancel As
Boolean)
    ' DragInfo.Layer = 9
    ' Layers(DragInfo.Layer).OnDrag = 2
End Sub
```

With Gauge1

.PicturesPath = "C:\Program

Files\Exontrol\ExGauge\Sample\Design\Circular\Knob"

.PicturesName = "`Layer` + int(value + 1) + `.png`"

.Layers.Count = 11

End With

VB.NET

' DragStart event - Occurs once the user starts dragging a layer.

Private Sub Exgauge1_DragStart(ByVal sender As System.Object, ByVal DragInfo As exontrol.EXGAUGELib.DragInfo, ByRef Cancel As Boolean) Handles

Exgauge1.DragStart

' DragInfo.Layer = 9

' Layers(DragInfo.Layer).OnDrag = 2

End Sub

With Exgauge1

.PicturesPath = "C:\Program

Files\Exontrol\ExGauge\Sample\Design\Circular\Knob"

.PicturesName = "`Layer` + int(value + 1) + `.png`"

.Layers.Count = 11

End With

VB.NET for /COM

' DragStart event - Occurs once the user starts dragging a layer.

Private Sub AxGauge1_DragStart(ByVal sender As System.Object, ByVal e As AxEXGAUGELib._IGaugeEvents_DragStartEvent) Handles AxGauge1.DragStart

' DragInfo.Layer = 9

' Layers(DragInfo.Layer).OnDrag = 2

End Sub

With AxGauge1

property DragInfo.RotateAngleValid as String

Validates the rotation angle of the layer, during dragging.

Type	Description
String	A String that indicates the expression to validate the rotation angle of the layer, during dragging.

The RotateAngleValid property specifies an expression that validates the rotation angle of the layer, during dragging operation. If using, the RotateAngleValid property should be called during the [DragStart](#) event. For instance, it is known that any layer can be rotated from 0 to 360% degree, but what about limitation of the rotation based on the mouse movement. In other words, if you rotate the clockwise the layer you want to prevent the layer to exceed the max value, so the RotateAngleValid property does the trick. The [DeltaAngle](#) property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation. The [RotateAngle](#) property specifies the current angle of the rotation of the specified layer. The [CumulativeRotateAngle](#) property specifies the cumulative rotation angle, during the dragging operation. The [Clockwise](#) property indicates if the rotation is clockwise or anticlockwise. A clockwise (typically abbreviated as CW) motion is one that proceeds in the same direction as a clock's hands: from the top to the right, then down and then to the left, and back up to the top. The [RotateAngleValid](#) property validates / limits the rotation angle of the layer.

For instance, RotateAngleValid = "value < 0 ? 0 : (value > 360 ? 359.999999 : value)", validates the rotation-angle so it always will be between 0 and 360, in other words limits the rotation angle.

The Exontrol's [eXpression](#) component is a syntax-editor that helps you to define, view, edit and evaluate expressions. Using the eXpression component you can easily view or check if the expression you have used is syntactically correct, and you can evaluate what is the result you get giving different values to be tested. The Exontrol's eXpression component can be used as an user-editor, to configure your applications.

The **value** keyword indicates the cumulative rotation angle ([CumulativeRotateAngle](#) property), during the dragging operation.

The constants are (DPI-Aware components):

- **dpi** (DPI constant), specifies the current DPI setting. and it indicates the minimum value between **dpix** and **dpiy** constants. For instance, if current DPI setting is 100%, the dpi constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpi returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%
- **dpix** (DPiX constant), specifies the current DPI setting on x-scale. For instance, if

current DPI setting is 100%, the dpix constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpix returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%

- **dpiy** (DPIY constant), specifies the current DPI setting on x-scale. For instance, if current DPI setting is 100%, the dpiy constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpiy returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%

The supported binary arithmetic operators are:

- * (multiplicity operator), priority 5
- / (divide operator), priority 5
- **mod** (reminder operator), priority 5
- + (addition operator), priority 4 (concatenates two strings, if one of the operands is of string type)
- - (subtraction operator), priority 4

The supported unary boolean operators are:

- **not** (not operator), priority 3 (high priority)

The supported binary boolean operators are:

- **or** (or operator), priority 2
- **and** (or operator), priority 1

The supported binary boolean operators, all these with the same priority 0, are :

- < (less operator)
- <= (less or equal operator)
- = (equal operator)
- != (not equal operator)
- >= (greater or equal operator)
- > (greater operator)

The supported binary range operators, all these with the same priority 5, are :

- **MIN** (min operator), indicates the minimum value, so a **MIN** b returns the value of a, if it is less than b, else it returns b. For instance, the expression value MIN 10 returns always a value greater than 10.
- **MAX** (max operator), indicates the maximum value, so a **MAX** b returns the value of a, if it is greater than b, else it returns b. For instance, the expression value MAX 100 returns always a value less than 100.

The supported binary operators, all these with the same priority 0, are :

- **:= (Store operator)**, stores the result of expression to variable. The syntax for := operator is

variable := expression

where variable is a integer between 0 and 9. You can use the := operator to restore any stored variable (please make the difference between := and =:). For instance, `(0:=dbl(value)) = 0 ? "zero" : =:0`, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the := and =: are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

- **=: (Restore operator)**, restores the giving variable (previously saved using the store operator). The syntax for =: operator is

=: variable

where variable is a integer between 0 and 9. You can use the =: operator to store the value of any expression (please make the difference between := and =:). For instance, `(0:=dbl(value)) = 0 ? "zero" : =:0`, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the := and =: are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

The supported ternary operators, all these with the same priority 0, are :

- **? (Immediate If operator)**, returns and executes one of two expressions, depending on the evaluation of an expression. The syntax for ? operator is

expression ? true_part : false_part

, while it executes and returns the true_part if the expression is true, else it executes and returns the false_part. For instance, the `%0 = 1 ? 'One' : (%0 = 2 ? 'Two' : 'not found')` returns 'One' if the value is 1, 'Two' if the value is 2, and 'not found' for any other value. A n-ary equivalent operation is the case() statement, which is available in newer versions of the component.

The supported n-ary operators are (with priority 5):

- **array (at operator)**, returns the element from an array giving its index (0 base). The array operator returns empty if the element is found, else the associated element in the collection if it is found. The syntax for array operator is

expression array (c1,c2,c3,...cn)

, where the c1, c2, ... are constant elements. The constant elements could be numeric, date or string expressions. For instance the *month(value)-1* array ('J','F','M','A','M','Jun','J','A','S','O','N','D') is equivalent with *month(value)-1* case (default:"; 0:'J';1:'F';2:'M';3:'A';4:'M';5:'Jun';6:'J';7:'A';8:'S';9:'O';10:'N';11:'D').

- **in** (*include operator*), specifies whether an element is found in a set of constant elements. The *in* operator returns -1 (True) if the element is found, else 0 (false) is retrieved. The syntax for *in* operator is

expression in (c1,c2,c3,...cn)

, where the c1, c2, ... are constant elements. The constant elements could be numeric, date or string expressions. For instance the *value in (11,22,33,44,13)* is equivalent with (*expression = 11*) or (*expression = 22*) or (*expression = 33*) or (*expression = 44*) or (*expression = 13*). The *in* operator is not a time consuming as the equivalent *or* version is, so when you have large number of constant elements it is recommended using the *in* operator. Shortly, if the collection of elements has 1000 elements the *in* operator could take up to 8 operations in order to find if an element fits the set, else if the *or* statement is used, it could take up to 1000 operations to check, so by far, the *in* operator could save time on finding elements within a collection.

- **switch** (*switch operator*), returns the value being found in the collection, or a predefined value if the element is not found (default). The syntax for *switch* operator is

expression switch (default,c1,c2,c3,...,cn)

, where the c1, c2, ... are constant elements, and the default is a constant element being returned when the element is not found in the collection. The constant elements could be numeric, date or string expressions. The equivalent syntax is "%0 = c 1 ? c 1 : (%0 = c 2 ? c 2 : (... ? : default))". The *switch* operator is very similar with the *in* operator excepts that the first element in the switch is always returned by the statement if the element is not found, while the returned value is the value itself instead -1. For instance, the %0 *switch* ('not found',1,4,7,9,11) gets 1, 4, 7, 9 or 11, or 'not found' for any other value. As the *in* operator the *switch* operator uses binary searches for fitting the element, so it is quicker than the *if* (immediate if operator) alternative.

- **case()** (*case operator*) returns and executes one of n expressions, depending on the evaluation of the expression (*IIF* - immediate IF operator is a binary *case()* operator). The syntax for *case()* operator is:

expression case ([default : default_expression ;] c1 : expression1 ; c2 : expression2 ; c3 : expression3 ;....)

If the default part is missing, the `case()` operator returns the value of the expression if it is not found in the collection of cases (`c1, c2, ...`). For instance, if the value of expression is not any of `c1, c2,` the `default_expression` is executed and returned. If the value of the expression is `c1`, then the `case()` operator executes and returns the *expression1*. The *default, c1, c2, c3, ...* must be constant elements as numbers, dates or strings. For instance, the `date(shortdate(value)) case (default:0 ; #1/1/2002#:1 ; #2/1/2002#:1; #4/1/2002#:1; #5/1/2002#:1)` indicates that only `#1/1/2002#, #2/1/2002#, #4/1/2002# and #5/1/2002#` dates returns 1, since the others returns 0. For instance the following sample specifies the hour being non-working for specified dates: `date(shortdate(value)) case(default:0;#4/1/2009# : hour(value) >= 6 and hour(value) <= 12 ; #4/5/2009# : hour(value) >= 7 and hour(value) <= 10 or hour(value) in(15,16,18,22); #5/1/2009# : hour(value) <= 8)` statement indicates the working hours for dates as follows:

- `#4/1/2009#`, from hours 06:00 AM to 12:00 PM
- `#4/5/2009#`, from hours 07:00 AM to 10:00 AM and hours 03:00PM, 04:00PM, 06:00PM and 10:00PM
- `#5/1/2009#`, from hours 12:00 AM to 08:00 AM

The *in*, *switch* and *case()* use binary search to look for elements so they are faster then using *iif* and *or* expressions. Obviously, the priority of the operations inside the expression is determined by () parenthesis and the priority for each operator.

The supported conversion unary operators are:

- **type** (unary operator) retrieves the type of the object. For instance `type(%1) = 8` specifies the cells (on the column 1) that contains string values.

Here's few predefined types:

- 0 - empty (not initialized)
- 1 - null
- 2 - short
- 3 - long
- 4 - float
- 5 - double
- 6 - currency
- 7 - date
- 8 - string
- 9 - object
- 10 - error
- 11 - boolean
- 12 - variant

- 13 - any
- 14 - decimal
- 16 - char
- 17 - byte
- 18 - unsigned short
- 19 - unsigned long
- 20 - long on 64 bits
- 21 - unsigned long on 64 bites
- **str** (unary operator) converts the expression to a string. The str operator converts the expression to a string. For instance, the *str(-12.54)* returns the string "-12.54".
- **dbl** (unary operator) converts the expression to a number. The dbl operator converts the expression to a number. For instance, the *dbl("12.54")* returns 12.54
- **date** (unary operator) converts the expression to a date, based on your regional settings. For instance, the *date(``)* gets the current date (no time included), the *date(`now`)* gets the current date-time, while the *date("01/01/2001")* returns #1/1/2001#
- **dateS** (unary operator) converts the string expression to a date using the format MM/DD/YYYY HH:MM:SS. For instance, the *dateS("01/01/2001 14:00:00")* returns #1/1/2001 14:00:00#

Other known operators for numbers are:

- **int** (unary operator) retrieves the integer part of the number. For instance, the *int(12.54)* returns 12
- **round** (unary operator) rounds the number ie 1.2 gets 1, since 1.8 gets 2. For instance, the *round(12.54)* returns 13
- **floor** (unary operator) returns the largest number with no fraction part that is not greater than the value of its argument. For instance, the *floor(12.54)* returns 12
- **abs** (unary operator) retrieves the absolute part of the number ie -1 gets 1, 2 gets 2. For instance, the *abs(-12.54)* returns 12.54
- **sin** (unary operator) returns the sine of an angle of x radians. For instance, the *sin(3.14)* returns 0.001593.
- **cos** (unary operator) returns the cosine of an angle of x radians. For instance, the *cos(3.14)* returns -0.999999.
- **asin** (unary operator) returns the principal value of the arc sine of x, expressed in radians. For instance, the *2*asin(1)* returns the value of PI.
- **acos** (unary operator) returns the principal value of the arc cosine of x, expressed in radians. For instance, the *2*acos(0)* returns the value of PI
- **sqrt** (unary operator) returns the square root of x. For instance, the *sqrt(81)* returns 9.
- **currency** (unary operator) formats the giving number as a currency string, as indicated by the control panel. For instance, *currency(value)* displays the value using the current format for the currency ie, 1000 gets displayed as \$1,000.00, for US format.

- value **format** 'flags' (binary operator) formats the value with specified flags. If flags is empty, the number is displayed as shown in the field "Number" in the "Regional and Language Options" from the Control Panel. For instance the *1000 format* " displays 1,000.00 for English format, while 1.000,00 is displayed for German format. 1000 format '2|.|3|,' will always displays 1,000.00 no matter of settings in the control panel. If formatting the number fails for some invalid parameter, the value is displayed with no formatting.

The ' flags' for format operator is a list of values separated by | character such as '*NumDigits|DecimalSep|Grouping|ThousandSep|NegativeOrder|LeadingZero*' with the following meanings:

- *NumDigits* - specifies the number of fractional digits, If the flag is missing, the field "No. of digits after decimal" from "Regional and Language Options" is using.
- *DecimalSep* - specifies the decimal separator. If the flag is missing, the field "Decimal symbol" from "Regional and Language Options" is using.
- *Grouping* - indicates the number of digits in each group of numbers to the left of the decimal separator. Values in the range 0 through 9 and 32 are valid. The most significant grouping digit indicates the number of digits in the least significant group immediately to the left of the decimal separator. Each subsequent grouping digit indicates the next significant group of digits to the left of the previous group. If the last value supplied is not 0, the remaining groups repeat the last group. Typical examples of settings for this member are: 0 to group digits as in 123456789.00; 3 to group digits as in 123,456,789.00; and 32 to group digits as in 12,34,56,789.00. If the flag is missing, the field "Digit grouping" from "Regional and Language Options" indicates the grouping flag.
- *ThousandSep* - specifies the thousand separator. If the flag is missing, the field "Digit grouping symbol" from "Regional and Language Options" is using.
- *NegativeOrder* - indicates the negative number mode. If the flag is missing, the field "Negative number format" from "Regional and Language Options" is using. The valid values are 0, 1, 2, 3 and 4 with the following meanings:
 - 0 - Left parenthesis, number, right parenthesis; for example, (1.1)
 - 1 - Negative sign, number; for example, -1.1
 - 2 - Negative sign, space, number; for example, - 1.1
 - 3 - Number, negative sign; for example, 1.1-
 - 4 - Number, space, negative sign; for example, 1.1 -
- *LeadingZero* - indicates if leading zeros should be used in decimal fields. If the flag is missing, the field "Display leading zeros" from "Regional and Language Options" is using. The valid values are 0, 1

Other known operators for strings are:

- **len** (unary operator) retrieves the number of characters in the string. For instance, the

len("Mihai") returns 5.

- **lower** (unary operator) returns a string expression in lowercase letters. For instance, the *lower("MIHAI")* returns "mihai"
- **upper** (unary operator) returns a string expression in uppercase letters. For instance, the *upper("mihai")* returns "MIHAI"
- **proper** (unary operator) returns from a character expression a string capitalized as appropriate for proper names. For instance, the *proper("mihai")* returns "Mihai"
- **ltrim** (unary operator) removes spaces on the left side of a string. For instance, the *ltrim(" mihai")* returns "mihai"
- **rtrim** (unary operator) removes spaces on the right side of a string. For instance, the *rtrim("mihai ")* returns "mihai"
- **trim** (unary operator) removes spaces on both sides of a string. For instance, the *trim(" mihai ")* returns "mihai"
- **reverse** (unary operator) reverses the order of the characters in the string a. For instance, the *reverse("Mihai")* returns "iahIM"
- **startswith** (binary operator) specifies whether a string starts with specified string (0 if not found, -1 if found). For instance *"Mihai" startswith "Mi"* returns -1
- **endwith** (binary operator) specifies whether a string ends with specified string (0 if not found, -1 if found). For instance *"Mihai" endwith "ai"* returns -1
- **contains** (binary operator) specifies whether a string contains another specified string (0 if not found, -1 if found). For instance *"Mihai" contains "ha"* returns -1
- **left** (binary operator) retrieves the left part of the string. For instance *"Mihai" left 2* returns "Mi".
- **right** (binary operator) retrieves the right part of the string. For instance *"Mihai" right 2* returns "ai"
- a **lfind** b (binary operator) The a lfind b (binary operator) searches the first occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" lfind "C"* returns 2
- a **rfind** b (binary operator) The a rfind b (binary operator) searches the last occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" rfind "C"* returns 5.
- a **mid** b (binary operator) retrieves the middle part of the string a starting from b (1 means first position, and so on). For instance *"Mihai" mid 2* returns "ihai"
- a **count** b (binary operator) retrieves the number of occurrences of the b in a. For instance *"Mihai" count "i"* returns 2.
- a **replace** b with c (double binary operator) replaces in a the b with c, and gets the result. For instance, the *"Mihai" replace "i" with ""* returns "Mha" string, as it replaces all "i" with nothing.
- a **split** b, splits the a using the separator b, and returns an array. For instance, the *weekday(value) array 'Sun Mon Thu Wed Thu Fri Sat' split ' '* gets the weekday as string. This operator can be used with the array.

Other known operators for dates are:

- **time** (unary operator) retrieves the time of the date in string format, as specified in the control's panel. For instance, the *time(#1/1/2001 13:00#)* returns "1:00:00 PM"
- **timeF** (unary operator) retrieves the time of the date in string format, as "HH:MM:SS". For instance, the *timeF(#1/1/2001 13:00#)* returns "13:00:00"
- **shortdate** (unary operator) formats a date as a date string using the short date format, as specified in the control's panel. For instance, the *shortdate(#1/1/2001 13:00#)* returns "1/1/2001"
- **shortdateF** (unary operator) formats a date as a date string using the "MM/DD/YYYY" format. For instance, the *shortdateF(#1/1/2001 13:00#)* returns "01/01/2001"
- **dateF** (unary operator) converts the date expression to a string expression in "MM/DD/YYYY HH:MM:SS" format. For instance, the *dateF(#01/01/2001 14:00:00#)* returns #01/01/2001 14:00:00#
- **longdate** (unary operator) formats a date as a date string using the long date format, as specified in the control's panel. For instance, the *longdate(#1/1/2001 13:00#)* returns "Monday, January 01, 2001"
- **year** (unary operator) retrieves the year of the date (100,...,9999). For instance, the *year(#12/31/1971 13:14:15#)* returns 1971
- **month** (unary operator) retrieves the month of the date (1, 2,...,12). For instance, the *month(#12/31/1971 13:14:15#)* returns 12.
- **day** (unary operator) retrieves the day of the date (1, 2,...,31). For instance, the *day(#12/31/1971 13:14:15#)* returns 31
- **yearday** (unary operator) retrieves the number of the day in the year, or the days since January 1st (0, 1,...,365). For instance, the *yearday(#12/31/1971 13:14:15#)* returns 365
- **weekday** (unary operator) retrieves the number of days since Sunday (0 - Sunday, 1 - Monday,..., 6 - Saturday). For instance, the *weekday(#12/31/1971 13:14:15#)* returns 5.
- **hour** (unary operator) retrieves the hour of the date (0, 1, ..., 23). For instance, the *hour(#12/31/1971 13:14:15#)* returns 13
- **min** (unary operator) retrieves the minute of the date (0, 1, ..., 59). For instance, the *min(#12/31/1971 13:14:15#)* returns 14
- **sec** (unary operator) retrieves the second of the date (0, 1, ..., 59). For instance, the *sec(#12/31/1971 13:14:15#)* returns 15

How can I limit the rotation from 0 to 360 degree, while dragging?

property DragInfo.UserData as Variant

Indicates any extra data associated with the dragging data.

Type	Description
Variant	A Variant expression that specifies any extra data associated with the drag operation.

By default, the UserData property is empty. Use the UserData property to store any extra data with the drag operation. You can set the UserData property during the [DragStart](#) event, and use it later during the [Drag](#) or [DragEnd](#) event. The [UserData](#) property of the Layer indicates any extra data associated with the layer.

property DragInfo.X as Long

Indicates the x-position of the cursor, when the drag operation starts.

Type	Description
Long	A Long expression that indicates the x-position of the cursor, when the drag operation starts.

The [X](#) / [Y](#) property indicates the (x,y)-position of the cursor, relative to the upper-left corner of the control, when dragging operation begins. The [OffsetX](#) / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [OffsetXValid](#) / [OffsetYValid](#) property to validate the (x,y)-position of the layer. For instance, you can use the [OffsetYValid](#) property on "0", and so no vertical movement is allowed.

The following properties can be used during dragging to determine the horizontal / vertical offset:

- [X](#) property indicates the x-position of the cursor, when the drag operation starts.
- [Y](#) property indicates the y-position of the cursor, when the drag operation starts.
- [CurrentX](#) property indicates the current x-position of the cursor, while dragging the layer.
- [CurrentY](#) property indicates the current y-position of the cursor, while dragging the layer.
- [Delta](#) property, returns the distance between clicking and current points.
- [DeltaX](#) property returns the offset on the x-coordinate of the the current drag operation, equivalent with the value of $\text{CurrentX} - X$.
- [DeltaY](#) property returns the offset on the y-coordinate of the the current drag operation, equivalent with the value of $\text{CurrentY} - Y$.

The [DeltaAngle](#) property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation.

property DragInfo.Y as Long

Indicates the y-position of the cursor, when the drag operation starts.

Type	Description
Long	A Long expression that indicates the y-position of the cursor, when the drag operation starts.

The [X](#) / [Y](#) property indicates the (x,y)-position of the cursor, relative to the upper-left corner of the control, when dragging operation begins. The [OffsetX](#) / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [OffsetXValid](#) / [OffsetYValid](#) property to validate the (x,y)-position of the layer. For instance, you can use the [OffsetXValid](#) property on "0", and so no horizontal movement is allowed.

The following properties can be used during dragging to determine the horizontal / vertical offset:

- [X](#) property indicates the x-position of the cursor, when the drag operation starts.
- [Y](#) property indicates the y-position of the cursor, when the drag operation starts.
- [CurrentX](#) property indicates the current x-position of the cursor, while dragging the layer.
- [CurrentY](#) property indicates the current y-position of the cursor, while dragging the layer.
- [Delta](#) property, returns the distance between clicking and current points.
- [DeltaX](#) property returns the offset on the x-coordinate of the the current drag operation, equivalent with the value of $\text{CurrentX} - X$.
- [DeltaY](#) property returns the offset on the y-coordinate of the the current drag operation, equivalent with the value of $\text{CurrentY} - Y$.

The [DeltaAngle](#) property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation.

Foreground object

The Foreground object holds HTML captions to be shown on the layer's foreground. The [Background](#) object holds pictures to be shown on the layer's background. The [Foreground](#) property of the Layer access the layer's Foreground object. The layer's foreground can be visible or selectable. If not selectable, the user can not select it runtime, such as LayerFromPoint property ignores it. The Layer's foreground can display unlimited HTML captions of different sizes and positions.

The following screen shot shows all layer's background with a semi-transparent color, to highlight the layer's foreground:

The Foreground object supports the following properties and methods:

Name	Description
Caption	Specifies the caption on the layer.
Color	Specifies the layer's foreground color.
ExtraCaption	Specifies any extra caption on the layer.
Selectable	Returns or sets a value that indicates whether all objects on the layer's foreground are selectable.
Visible	Specifies if the objects of the layer's foreground are shown or hidden.

Property Foreground.Caption(Property as PropertyLayerCaptionEnum) as Variant

Specifies the caption on the layer.

Type	Description
Property as PropertyLayerCaptionEnum	A PropertyLayerCaptionEnum expression that specifies the caption's property to be changed.
Variant	A VARIANT expression that specifies the value of the caption's property.

The control support unlimited HTML captions to be place anywhere on the control or on any layer of the control. The Caption(exLayerCaption) specifies the HTML caption to be shown on the control/layer. The [Images](#) method specifies the list of icons the control can display. The [HTMLPicture](#) adds or replaces a picture in HTML captions. The Caption(exLayerCaptionBackgroundExt) property indicates unlimited options to show any HTML text, images, colors, EBNs, patterns, frames anywhere on the control / layer's background. The caption on the control stay on its position, no matter what layer is moved or rotated, while a caption on a layer gets moved or rotated together with the layer itself. The [Color](#) property specifies the caption's foreground color.

Any of the following properties can be used to display a HTML caption:

- [Caption](#) property specifies the caption to be shown on the control's foreground.
- [ExtraCaption](#) property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

The following screen shot shows an extra-caption associated with the layer:

The following samples show how you can associate an extra-caption with a layer:

Property Foreground.Color as Color

Specifies the layer's foreground color.

Type	Description
Color	A Color expression that specifies the caption's foreground color.

By default, the Color property is -1, which indicates that has no effect. The Color property specifies the caption's foreground color. The [Visible](#) property shows or hides all layer's caption / extra-captions. The [Selectable](#) property makes all layer' captions / extra-captions selectable or unselectable.

Any of the following properties can be used to display a HTML caption:

- [Caption](#) property specifies the caption to be shown on the control's foreground.
- [ExtraCaption](#) property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

property Foreground.ExtraCaption(Key as Variant, Property as PropertyLayerCaptionEnum) as Variant

Specifies any extra caption on the layer.

Type	Description
Key as Variant	Any VARIANT expression that indicates the key of the extra caption. You can use any value to identify your extra caption.
Property as PropertyLayerCaptionEnum	A PropertyLayerCaptionEnum expression that specifies the extra caption's property to be changed.
Variant	A VARIANT expression that specifies the value of the extra caption's property.

The control support unlimited HTML captions to be place anywhere on the control or on any layer of the control. The Caption(exLayerCaption) specifies the HTML caption to be shown on the control/layer. The [Images](#) method specifies the list of icons the control can display. The [HTMLPicture](#) adds or replaces a picture in HTML captions. The Caption(exLayerCaptionBackgroundExt) property indicates unlimited options to show any HTML text, images, colors, EBNs, patterns, frames anywhere on the control / layer's background. The caption on the control stay on its position, no matter what layer is moved or rotated, while a caption on a layer gets moved or rotated together with the layer itself.

Any of the following properties can be used to display a HTML caption:

- [Caption](#) property specifies the caption to be shown on the control's foreground.
- [ExtraCaption](#) property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

The following screen shot shows an extra-caption associated with the layer:

The following samples show how you can associate an extra-caption with a layer:

property Foreground.Selectable as Boolean

Returns or sets a value that indicates whether all objects on the layer's foreground are selectable.

Type	Description
Boolean	A Boolean expression that specifies whether the layer's foreground is selectable or unselectable.

By default, the Selectable property is True. The Selectable property makes all layer' captions / extra-captions selectable or unselectable. The [Grayscale](#) property returns or sets a value that indicates whether the layer is show as grayscale. For instance, you can simulate a disabled layer by changing the layer's Grayscale property on True, and setting the layer's Selectable property on False. The [Visible](#) property shows or hides all layer's caption / extra-captions.

Any of the following properties can be used to display a HTML caption:

- [Caption](#) property specifies the caption to be shown on the control's foreground.
- [ExtraCaption](#) property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

property Foreground.Visible as Boolean

Specifies if the objects of the layer's foreground are shown or hidden.

Type	Description
Boolean	A Boolean expression that specifies whether layer's foreground is visible or hidden.

By default, the Visible property is True. The Visible property shows or hides all layer's caption / extra-captions. The [Selectable](#) property makes all layer' captions / extra-captions selectable or unselectable.

Any of the following properties can be used to display a HTML caption:

- [Caption](#) property specifies the caption to be shown on the control's foreground.
- [ExtraCaption](#) property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

Gauge object

Tip The /COM object can be placed on a HTML page (with usage of the HTML object tag: <object classid="clsid:...">) using the class identifier: {91628F12-393C-44EF-A558-83ED1790AAD3}. The object's program identifier is: "Exontrol.Gauge". The /COM object module is: "ExGauge.dll"

The eXGauge / eXLayers library provides graphics capabilities to visually display and edit the amount, level, or contents of something. The view can show one or more layers, where each layer can display one or more transparent pictures, HTML captions which can be clipped, moved, rotated or combination of them, by dragging the mouse, rolling the mouse wheel, or using the keyboard. Using the eXGauge / eXLayers library you can easily simulate any gauges, thermometers, meters, clocks, buttons, sliders, scales, knobs, dials, switches, progress, status, indicators, LEDs, and so on. As usual, there are no dependencies to MFC, VB, VCL, or anything else.

The following screen shot shows the idea of having multiple layers that are transparent and you can adjust the offset of the images, the transparency levels and rotate each image to create different types of gauges simple by changing the layer graphics:

The following table shows how you can create / access different type of objects (red items indicates the name of the property/method):

EXGAUGELib.Gauge
"Layers" -> EXGAUGELib.Layers

"VisualAppearance" -> EXGAUGELib.Appearance

EXGAUGELib.Layers

"Add(Variant)" -> EXGAUGELib.Layer

"Item(Variant)" -> EXGAUGELib.Layer

"VisibleItem(Long)" -> EXGAUGELib.Layer

EXGAUGELib.Layer

"Background" -> EXGAUGELib.Background

"Clip" -> EXGAUGELib.Clip

"Foreground" -> EXGAUGELib.Foreground

EXGAUGELib.Background

"Color" -> EXGAUGELib.Color

"ExtraPicture(Variant)" -> EXGAUGELib.Picture

"Picture" -> EXGAUGELib.Picture

EXGAUGELib.Clip

"Ellipse" -> EXGAUGELib.ClipEllipse

"Picture" -> EXGAUGELib.ClipPicture

"Pie" -> EXGAUGELib.ClipPie

"Polygon" -> EXGAUGELib.ClipPolygon

"Rectangle" -> EXGAUGELib.ClipRectangle

"RoundRectangle" -> EXGAUGELib.ClipRoundRectangle

The following table shows how you can create / access different type of objects (red items indicates the name of the property/method):

EXGAUGELib.Appearance <- "VisualAppearance" of EXGAUGELib.Gauge

EXGAUGELib.Background <- "Background" of EXGAUGELib.Layer

EXGAUGELib.Clip <- "Clip" of EXGAUGELib.Layer

EXGAUGELib.ClipEllipse <- "Ellipse" of EXGAUGELib.Clip

EXGAUGELib.ClipPicture <- "Picture" of EXGAUGELib.Clip

EXGAUGELib.ClipPie <- "Pie" of EXGAUGELib.Clip

EXGAUGELib.ClipPolygon <- "Polygon" of EXGAUGELib.Clip

EXGAUGELib.ClipRectangle <- "Rectangle" of EXGAUGELib.Clip

EXGAUGELib.ClipRoundRectangle <- "RoundRectangle" of EXGAUGELib.Clip

EXGAUGELib.Color <- "Color" of EXGAUGELib.Background

EXGAUGELib.Foreground <- "Foreground" of EXGAUGELib.Layer

EXGAUGELib.Layer <- "Add(Variant)" of EXGAUGELib.Layers

EXGAUGELib.Layer <- "Item(Variant)" of EXGAUGELib.Layers

EXGAUGELib.Layer <- "VisibleItem(Long)" of EXGAUGELib.Layers

EXGAUGELib.Layers <- "Layers" of EXGAUGELib.Gauge
EXGAUGELib.Picture <- "ExtraPicture(Variant)" of EXGAUGELib.Background
EXGAUGELib.Picture <- "Picture" of EXGAUGELib.Background

The Gauge object supports the following properties and methods:

Name	Description
AllowCopyTemplate	Specifies whether the Shift + Ctrl + Alt + Insert sequence copies the control's content to the clipboard, in template form.
AllowMoveOnClick	Allows moving the window that contains the control to a new position, as you would do by clicking the form's title/caption.
AllowSmoothChange	Specifies the properties of the layers that support smooth change.
AnchorFromPoint	Retrieves the identifier of the anchor from point.
Appearance	Retrieves or sets the control's appearance.
AttachTemplate	Attaches a script to the current object, including the events, from a string, file, a safe array of bytes.
BackColor	Specifies the control's background color.
Background	Returns or sets a value that indicates the background color for parts in the control.
BeginUpdate	Maintains performance when items are added to the control one at a time. This method prevents the control from painting until the EndUpdate method is called.
Caption	Specifies the caption on the control.
CopyTo	Exports the control's view to an EMF file.
Debug	Displays the control in debug mode.
DefaultLayer	Defines the default value for properties of the layers to be created.
Enabled	Enables or disables the control.
EndUpdate	Resumes painting the control after painting is suspended by the BeginUpdate method.
EventParam	Retrieves or sets a value that indicates the current's event parameter.
ExecuteTemplate	Executes a template and returns the result.

ExtraCaption	Specifies any extra caption on the control.
Font	Retrieves or sets the control's font.
ForeColor	Specifies the control's foreground color.
FormatABC	Formats the A,B,C values based on the giving expression and returns the result.
FormatAnchor	Specifies the visual effect for anchor elements in HTML captions.
FreezeEvents	Prevents the control to fire any event.
HTMLPicture	Adds or replaces a picture in HTML captions.
hWnd	Retrieves the control's window handle.
Images	Sets at runtime the control's image list. The Handle should be a handle to an Images List Control.
ImageSize	Retrieves or sets the size of icons the control displays..
LayerAutoSize	Specifies the index of the layer that determines the size to display all layers.
LayerClipTo	Specifies the index of the layer that clips the entire control to.
LayerClipToParent	Indicates if the LayerClipTo method clips the control itself, parent or the owner of the control.
LayerDragAny	Specifies the index of the layer to drag (rotate or move) once the user clicks anywhere on the control.
LayerFromPoint	Retrieves the index of the layer from the point (only visible and selectable objects are included).
LayerOfValue	Specifies the index of the layer whose value represents the control's Value property.
Layers	Returns the Layers collection.
LayerUpdate	Specifies where the control updates its content.
PicturesName	Specifies the expression that indicates the name of the picture to be loaded on each layer.
PicturesPath	Specifies the path to load the pictures from.
Refresh	Refreses the control.
Replacelcon	Adds a new icon, replaces an icon or clears the control's image list.
ShowImageList	Specifies whether the control's image list window is visible or hidden.

ShowLayers	Indicates the only layers to be shown on the control.
ShowToolTip	Shows the specified tooltip at given position.
Template	Specifies the control's template.
TemplateDef	Defines inside variables for the next Template/ExecuteTemplate call.
TemplatePut	Defines inside variables for the next Template/ExecuteTemplate call.
TimerInterval	Returns or sets the number of milliseconds between calls of control's Timer event.
ToolTipDelay	Specifies the time in ms that passes before the ToolTip appears.
ToolTipFont	Retrieves or sets the tooltip's font.
ToolTipPopDelay	Specifies the period in ms of time the ToolTip remains visible if the mouse pointer is stationary within a control.
ToolTipWidth	Specifies a value that indicates the width of the tooltip window, in pixels.
ToTemplate	Generates the control's template.
TransparentColorFrom	Specifies the transparent color for all pictures in all layers, to define transparency part (from).
TransparentColorTo	Specifies the transparent color for all pictures in all layers, to define transparency part (to).
Value	Specifies the control's value.
Version	Retrieves the control's version.
VisualAppearance	Retrieves the control's appearance.

property Gauge.AllowCopyTemplate as Boolean

Specifies whether the Shift + Ctrl + Alt + Insert sequence copies the control's content to the clipboard, in template form.

Type	Description
Boolean	A Boolean expression that specifies whether the Shift + Ctrl + Alt + Insert sequence copies the control's content to the clipboard, in template form.

By default, AllowCopyTemplate property is True (for evaluation version), and False (for registered version). The AllowCopyTemplate property specifies whether the Shift + Ctrl + Alt + Insert sequence copies the control's content to the clipboard, in template form. The AllowCopyTemplate property is available for /COM version only, and it was provided for a simple way of copying the control's content to template form, no matter of your programming language. The property uses the [ToTemplate](#) property to generate the control's template, at runtime. The format of the clipboard being copied is plain text. Use the [Template](#) property to apply the generated template to an empty control.

property Gauge.AllowMoveOnClick as Boolean

Allows moving the window that contains the control to a new position, as you would do by clicking the form's title/caption.

Type	Description
Boolean	A Boolean expression that specifies whether the user can move the control on the screen by clicking it.

By default, the AllowMoveOnClick property is False. The AllowMoveOnClick property allows moving the window that contains the control to a new position, as you would do by clicking the form's title/caption. For instance, you can use the AllowMoveOnClick property on True, when you create a widget to be displayed on the screen, and so the user can move the widget by clicking it.

You can use any of the following to convert your control to a widget:

- The [LayerClipTo](#) property specifies the index of the layer that clips the entire control to.
- The [LayerUpdate](#) property indicates where the control's content is updated.

property Gauge.AllowSmoothChange as SmoothPropertyEnum

Specifies the properties of the layers that support smooth change.

Type	Description
SmoothPropertyEnum	A SmoothPropertyEnum expression the properties of the layer that can be changed gradually.

By default, the AllowSmoothChange property is exLayerTransparency | exLayerBrightness | exLayerContrast. Use the AllowSmoothChange property to disable changing gradually any brightness / contrast or the transparency, of the layer. For instance, a gradually change means that you can change the layer's transparency from 0 to 50 in a short time, with intermediate values (smooth change).

The AllowSmoothChange property changes gradually one / or more properties like follow:

- [Brightness](#), Specifies the percent of brightness to apply to the layer.
- [Contrast](#), Specifies the percent of contrast to apply to the layer.
- [Transparency](#), Gets or sets a value that indicates percent of the transparency to display the layer.

The [MouseIn](#) / [MouseOut](#) event notifies your application when the cursor is entering / leaving the layer. The [MouseMove](#) event is generated continually as the mouse pointer moves across objects. The AllowSmoothChange property specifies the properties of the layers that support smooth change. For instance, you can use the MouseIn / MouseOut event to change gradually the brightness / contrast or the transparency, of the layer, while the AllowSmoothChange property is not exSmoothChangeless.

property Gauge.AnchorFromPoint (X as OLE_XPOS_PIXELS, Y as OLE_YPOS_PIXELS) as String

Retrieves the identifier of the anchor from point.

Type	Description
X as OLE_XPOS_PIXELS	A single that specifies the current X location of the mouse pointer. The x values is always expressed in client coordinates.
Y as OLE_YPOS_PIXELS	A single that specifies the current Y location of the mouse pointer. The y values is always expressed in client coordinates.
String	A String expression that specifies the identifier (id) of the anchor element from the point, or empty string if there is no anchor element at the cursor.

Use the AnchorFromPoint property to determine the identifier of the anchor from the point. Use the <a id;options> anchor elements to add hyperlinks to cell's caption. The control fires the [AnchorClick](#) event when the user clicks an anchor element. Use the [ShowToolTip](#) method to show the specified tooltip at given or cursor coordinates. The [MouseMove](#) event is generated continually as the mouse pointer moves across the control.

property Gauge.Appearance as AppearanceEnum

Retrieves or sets the control's appearance.

Type	Description
AppearanceEnum	An AppearanceEnum expression that indicates the control's appearance, or a color expression whose last 7 bits in the high significant byte of the value indicates the index of the skin in the Appearance collection, being displayed as control's borders. For instance, if the Appearance = 0x1000000, indicates that the first skin object in the Appearance collection defines the control's border. The Client object in the skin, defines the client area of the control.

Use the Appearance property to specify the control's border.

method Gauge.AttachTemplate (Template as Variant)

Attaches a script to the current object, including the events, from a string, file, a safe array of bytes.

Type	Description
Template as Variant	A string expression that specifies the Template to execute.

The AttachTemplate/x-script code is a simple way of calling control/object's properties, methods/events using strings. The AttachTemplate features allows you to attach a x-script code to the component. The AttachTemplate method executes x-script code (including events), from a string, file or a safe array of bytes. This feature allows you to run any x-script code for any configuration of the component /COM, /NET or /WPF. Exontrol owns the x-script implementation in its easiest form and it does not require any VB engine or whatever to get executed. The x-script code can be converted to several programming languages using the eXHelper tool.

The following sample opens the Windows Internet Explorer once the user clicks the control (/COM version):

```
AttachTemplate("handle Click(){ CreateObject(`internetexplorer.application`){ Visible = True; Navigate(`https://www.exontrol.com`) } } ")
```

This script is equivalent with the following VB code:

```
Private Sub Gauge1_Click()  
    With CreateObject("internetexplorer.application")  
        .Visible = True  
        .Navigate ("https://www.exontrol.com")  
    End With  
End Sub
```

The AttachTemplate/x-script syntax in BNF notation is defined like follows:

```
<x-script> := <lines>  
<lines> := <line>[<eol> <lines>] | <block>  
<block> := <call> [<eol>] { [<eol>] <lines> [<eol>] } [<eol>]  
<eol> := ";" | "\r\n"  
<line> := <dim> | <createobject> | <call> | <set> | <comment> | <handle>[<eol>][<eol>]  
<lines>[<eol>][<eol>]  
<dim> := "DIM" <variables>  
<variables> := <variable> [, <variables>]
```

```

<variable> := "ME" | <identifier>
<createobject> := "CREATEOBJECT(`"<type>`")"
<call> := <variable> | <property> | <variable>."<property>" | <createobject>."<property>"
<property> := [<property>"."]<identifier>["("<parameters>")"]
<set> := <call> "=" <value>
<property> := <identifier> | <identifier> "(" [<parameters>] ")"
<parameters> := <value> [","<parameters>]
<value> := <boolean> | <number> | <color> | <date> | <string> | <createobject> | <call>
<boolean> := "TRUE" | "FALSE"
<number> := "0X"<hexa> | ["-"]<integer>["."<integer>]
<digit10> := 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
<digit16> := <digit10> | A | B | C | D | E | F
<integer> := <digit10> [<integer>]
<hexa> := <digit16> [<hexa>]
<color> := "RGB("<integer>","<integer>","<integer>")"
<date> := "#"<integer>"/"<integer>"/"<integer>" "["<integer>":"<integer>":"<integer>"]"#
<string> := ""<text>"" | ""<text>""
<comment> := ""<text>
<handle> := "handle " <event>
<event> := <identifier> "(" [<eparameters>] ")"
<eparameters> := <eparameter> [","<eparameters>]
<parameters> := <identifier>

```

where:

<identifier> indicates an identifier of the variable, property, method or event, and should start with a letter.

<type> indicates the type the CreateObject function creates, as a progID for /COM version or the assembly-qualified name of the type to create for /NET or /WPF version

<text> any string of characters

The Template or x-script is composed by lines of instructions. Instructions are separated by "\n\r" (newline characters) or ";" character.

The advantage of the AttachTemplate relative to [Template](#) / [ExecuteTemplate](#) is that the AttachTemplate can add handlers to the control events.

property Gauge.BackColor as Color

Specifies the control's background color.

Type	Description
Color	A Color expression that indicates the control's background color.

The BackColor property specifies the control's background color. The [ForeColor](#) property specifies the control's foreground color.

Any of the following properties can be used to display a HTML caption:

- [Caption](#) property specifies the caption to be shown on the control's foreground.
- [ExtraCaption](#) property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

The following screen shot shows an extra-caption associated with the layer:

property Gauge.Background(Part as BackgroundPartEnum) as Color

Returns or sets a value that indicates the background color for parts in the control.

Type	Description
Part as BackgroundPartEnum	A BackgroundPartEnum expression that indicates a part in the control.
Color	A Color expression that indicates the background color for a specified part. The last 7 bits in the high significant byte of the color to indicates the identifier of the skin being used. Use the Add method to add new skins to the control. If you need to remove the skin appearance from a part of the control you need to reset the last 7 bits in the high significant byte of the color being applied to the background's part.

The Background property specifies a background color or a visual appearance for specific parts in the control. If the Background property is 0, the control draws the part as default. Use the [Add](#) method to add new skins to the control. Use the [Remove](#) method to remove a specific skin from the control. Use the [Clear](#) method to remove all skins in the control. Use the [BeginUpdate](#) and [EndUpdate](#) methods to maintain performance while init the control. Use the [Refresh](#) method to refresh the control.

For instance:

- Use the [Background\(exToolTipAppearance\)](#) property indicates the visual appearance of the borders of the tooltips
- Use the [Background\(exToolTipBackColor\)](#) property indicates the tooltip's background color
- Use the [Background\(exToolTipForeColor\)](#) property indicates the tooltip's foreground color.

Use the [ShowToolTip](#) method to display a custom tooltip. The [ToolTip](#) / [ToolTipTitle](#) property indicates the layer's tooltip. The [LayerFromPoint](#) property returns the index of the layer from the cursor. Use the [ToolTipWidth](#) property to specify the width of the tooltip window Use the [ToolTipPopDelay](#) property specifies the period in ms of time the ToolTip remains visible if the mouse pointer is stationary within a control. Use the [ToolTipFont](#) property to change the tooltip's font.

method Gauge.BeginUpdate ()

Maintains performance when items are added to the control one at a time. This method prevents the control from painting until the EndUpdate method is called.

Type	Description
------	-------------

Property Gauge.Caption(Property as PropertyLayerCaptionEnum) as Variant

Specifies the caption on the control.

Type	Description
Property as PropertyLayerCaptionEnum	A PropertyLayerCaptionEnum expression that specifies the caption's property to be changed.
Variant	A VARIANT expression that specifies the value of the caption's property.

The control support unlimited HTML captions to be place anywhere on the control or on any layer of the control. The Caption(exLayerCaption) specifies the HTML caption to be shown on the control/layer. The [Images](#) method specifies the list of icons the control can display. The [HTMLPicture](#) adds or replaces a picture in HTML captions. The Caption(exLayerCaptionBackgroundExt) property indicates unlimited options to show any HTML text, images, colors, EBNs, patterns, frames anywhere on the control / layer's background. The caption on the control stay on its position, no matter what layer is moved or rotated, while a caption on a layer gets moved or rotated or clipped together with the layer itself. The [Visible](#) property shows or hides all layer's caption / extra-captions. The [LayerToClientX](#) / [LayerToClientY](#) properties translate a point from the layer (as it is moved or rotated) to the control's view.

Any of the following properties can be used to display a HTML caption:

- Caption property specifies the caption to be shown on the control's foreground.
- [ExtraCaption](#) property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

The following screen shot shows a caption on the Top-Left side of the control, and one extra caption to to Bottom-Right side of the control:

The following samples show how you can place caption on the Top-Left side of the control, and one extra caption to to Bottom-Right side of the control:

VBA (MS Access, Excell...)

With Gauge1

```
.BeginUpdate
.HTMLPicture("logo") = "E:\Exontrol\Exontrol.Logo\exontrol.logo.png"

property Gauge.CopyTo (File as String) as Variant

Exports the control's view to an EMF file.

Type	Description
File as String	<p>A String expression that indicates the name of the file to be saved. If present, the CopyTo property retrieves True, if the operation succeeded, else False it is failed. If the File parameter is missing or empty, the CopyTo property retrieves an one dimension safe array of bytes that contains the EMF content.</p> <p>If the File parameter is not empty, the extension (characters after last dot) determines the graphical/ format of the file to be saved as follows:</p> <ul style="list-style-type: none">• *.bmp *.dib *.rle, saves the control's content in BMP format.• *.jpg *.jpe *.jpeg *.jfif, saves the control's content in JPEG format.• *.gif, , saves the control's content in GIF format.• *.tif *.tiff, saves the control's content in TIFF format.• *.png, saves the control's content in PNG format.• *.pdf, saves the control's content to PDF format. The File argument may carry up to 4 parameters separated by the character in the following order: <i>filename.pdf paper size margins options</i>. In other words, you can specify the file name of the PDF document, the paper size, the margins and options to build the PDF document. By default, the paper size is 210 mm × 297 mm (A4 format) and the margins are 12.7 mm 12.7 mm 12.7 mm 12.7 mm. The units for the paper size and margins can be pt for PostScript Points, mm for Millimeters, cm for Centimeters, in for Inches and px for pixels. If PostScript Points are used if unit is missing. For instance, 8.27 in x 11.69 in, indicates the size of the paper in inches. Currently, the options can be single, which indicates that the control's content is exported to a single PDF page. For instance, the CopyTo("shot.pdf 33.11 in x 46.81 in 0 0 0 0 single") exports the control's content to an A0 single PDF page, with no margins.• *.emf or any other extension determines the control to

save the control's content in **EMF** format.

For instance, the `CopyTo("c:\temp\snapshot.png")` property saves the control's content in PNG format to `snapshot.png` file.

Variant

A boolean expression that indicates whether the File was successful saved, if the File parameter is not empty, or a one dimension safe array of bytes, if the File parameter is empty string.

The `CopyTo` method copies/exports the control's view to BMP, PNG, JPG, GIF, TIFF, PDF or EMF graphical files.

- The **BMP** file format, also known as bitmap image file or device independent bitmap (DIB) file format or simply a bitmap, is a raster graphics image file format used to store bitmap digital images, independently of the display device (such as a graphics adapter)
- The **JPEG** file format (seen most often with the .jpg extension) is a commonly used method of lossy compression for digital images, particularly for those images produced by digital photography.
- The **GIF** (Graphics Interchange Format) is a bitmap image format that was introduced by CompuServe in 1987 and has since come into widespread usage on the World Wide Web due to its wide support and portability.
- The **TIFF** (Tagged Image File Format) is a computer file format for storing raster graphics images, popular among graphic artists, the publishing industry, and both amateur and professional photographers in general.
- The **PNG** (Portable Network Graphics) is a raster graphics file format that supports lossless data compression. PNG was created as an improved, non-patented replacement for Graphics Interchange Format (GIF), and is the most used lossless image compression format on the Internet
- The **PDF** (Portable Document Format) is a file format used to present documents in a manner independent of application software, hardware, and operating systems. Each PDF file encapsulates a complete description of a fixed-layout flat document, including the text, fonts, graphics, and other information needed to display it.
- The **EMF** (Enhanced Metafile Format) is a 32-bit format that can contain both vector information and bitmap information. This format is an improvement over the Windows Metafile Format and contains extended features, such as the following

Built-in scaling information

Built-in descriptions that are saved with the file

Improvements in color palettes and device independence

The EMF format is an extensible format, which means that a programmer can modify the original specification to add functionality or to meet specific needs. You can paste this format to Microsoft Word, Excel, Front Page, Microsoft Image Composer and any application that know to handle EMF formats.

The following VB sample saves the control's content to a EMF file:

```
If (Control.CopyTo("c:\temp\test.emf")) Then
    MsgBox "test.emf file created, open it using the mspaint editor."
End If
```

The following VB sample prints the EMF content (as bytes, File parameter is empty string):

```
Dim i As Variant
For Each i In Control.CopyTo("")
    Debug.Print i
Next
```

property Gauge.Debug as DebugLayerEnum

Displays the control in debug mode.

Type	Description
DebugLayerEnum	A DebugLayerEnum expression that indicates whether the control displays layers in debug mode.

By default, the Debug property is exNoDebugLayer. Use the Debug property to display the layers in debug mode. The [ShowLayers](#) property indicates the only layers to be shown on the control. The [Debug](#) property specifies debugging information to be shown while dragging the layers. Also, properties like [OnDrag](#), [LayerFromPoint](#) are not valid while the control is running in debug mode.

The following screen shot shows the control using pictures from the C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob folder (Debug property is exNoDebugLayer, default):

The following screen shot shows the control while Debug property is exDebugLayers:

property Gauge.DefaultLayer(Property as DefaultLayerPropertyEnum) as Variant

Defines the default value for properties of the layers to be created.

Type	Description
Property as DefaultLayerPropertyEnum	A DefaultLayerPropertyEnum expression that specifies the property to change the default value
Variant	A VARIANT expression that specifies the property's default value.

The DefaultLayer property defines the default value for properties of the layers to be created. Any call of the DefaultLayer property has effect for any new layer added to the control's collection. Changing the DefaultLayer property does not have any effect on already existing layers.

The following samples show how you can load all layers with a semi-transparency (50%):

VBA (MS Access, Excell...)

```
With Gauge1
    .AllowSmoothChange = 0
    .DefaultLayer(22) = 50
    .PicturesPath = "C:\Program Files
(x86)\Exontrol\ExGauge\Sample\Design\Circular\Knob"
    .PicturesName = "`Layer` + int(value + 1) + `.png`"
    .Layers.Count = 11
End With
```

property Gauge.Enabled as Boolean

Enables or disables the control.

Type	Description
Boolean	A boolean expression that determines whether an control can respond to user-generated events.

By default, the Enabled property is True. The Enabled property specifies whether the entire control is enabled or disabled. The [Selectable](#) property returns or sets a value that indicates whether the layer is selectable. You can use the [Grayscale](#) property to show the entire layer in gray scale (disable state). For instance, you can simulate a disabled layer by changing the layer's Grayscale property on True, and setting the layer's Selectable property on False.

method Gauge.EndUpdate ()

Resumes painting the control after painting is suspended by the BeginUpdate method.

Type	Description
------	-------------

property Gauge.EventParam(Parameter as Long) as Variant

Retrieves or sets a value that indicates the current's event parameter.

Type	Description
Parameter as Long	A long expression that indicates the index of the parameter being requested ie 0 means the first parameter, 1 means the second, and so on. If -1 is used the EventParam property retrieves the number of parameters. Accessing an not-existing parameter produces an OLE error, such as invalid pointer (E_POINTER)
Variant	A VARIANT expression that specifies the parameter's value.

The EventParam method is provided to allow changing the event's parameters passed by reference, even if your environment does not support changing it (uniPaas 1.5 (formerly known as eDeveloper), DBase, and so on). For instance, Unipaas event-handling logic cannot update ActiveX control variables by updating the received arguments. The EventParam(0) retrieves the value of the first parameter of the event, while the EventParam(1) = 0, changes the value of the second parameter to 0 (the operation is successfully, only if the parameter is passed by reference). The EventParam(-1) retrieves the number of the parameters of the current event.

Let's take the event "event KeyDown (**KeyCode** as Integer, ByVal Shift as Integer)", where the KeyCode parameter is passed by reference. For instance, put the KeyCode parameter on 0, and the arrow keys are disabled while the control has the focus.

In most languages you will type something like:

```
Private Sub Control1_KeyDown(KeyCode As Integer, Shift As Integer)
    KeyCode = 0
End Sub
```

In case your environment does not support events with parameters by reference, you can use a code like follows:

```
Private Sub Control1_KeyDown(KeyCode As Integer, Shift As Integer)
    Control1.EventParam(0) = 0
End Sub
```

In other words, the EventParam property provides the parameters of the current event for reading or writing access, even if your environment does not allow changing parameters by

reference.

Calling the EventParam property outside of an event produces an OLE error, such as pointer invalid, as its scope was designed to be used only during events.

method Gauge.ExecuteTemplate (Template as String)

Executes a template and returns the result.

Type	Description
Template as String	A Template string being executed
Return	Description
Variant	A Variant expression that indicates the result after executing the Template.

Use the ExecuteTemplate property to returns the result of executing a template file. Use the [Template](#) property to execute a template without returning any result. Use the ExecuteTemplate property to execute code by passing instructions as a string (template string).

For instance, the following sample retrieves the control's background color:

```
Debug.Print Gauge1.ExecuteTemplate("BackColor")
```

Most of our UI components provide a Template page that's accessible in design mode. No matter what programming language you are using, you can have a quick view of the component's features using the WYSWYG Template editor.

- Place the control to your form or dialog.
- Locate the Properties item, in the control's context menu, in design mode. If your environment doesn't provide a Properties item in the control's context menu, please try to locate in the Properties browser.
- Click it, and locate the Template page.
- Click the Help button. In the left side, you will see the component, in the right side, you will see a x-script code that calls methods and properties of the control.

The control's Template page helps user to initialize the control's look and feel in design mode, using the x-script language that's easy and powerful. The Template page displays the control on the left side of the page. On the right side of the Template page, a simple editor is displayed where user writes the initialization code. The control's look and feel is automatically updated as soon as the user types new instructions. The Template script is saved to the container persistence (when Apply button is pressed), and it is executed when the control is initialized at runtime. Any component that provides a WYSWYG Template page, provides a Template property. The Template property executes code from a string (template string).

The Template or x-script is composed by lines of instructions. Instructions are separated by "\n\r" (newline characters) or ";" character. The ; character may be available only for

newer versions of the components.

An x-script instruction/line can be one of the following:

- **Dim** list of variables *Declares the variables. Multiple variables are separated by commas. (Sample: Dim h, h1, h2)*
- variable = property(list of arguments) *Assigns the result of the property to a variable. The "variable" is the name of a declared variable. The "property" is the property name of the object in the context. The "list or arguments" may include variables or values separated by commas. (Sample: h = InsertItem(0,"New Child"))*
- property(list of arguments) = value *Changes the property. The value can be a variable, a string, a number, a boolean value or a RGB value.*
- method(list of arguments) *Invokes the method. The "list or arguments" may include variables or values separated by commas.*
- { *Beginning the object's context. The properties or methods called between { and } are related to the last object returned by the property prior to { declaration.*
- } *Ending the object's context*
- object. property(list of arguments).property(list of arguments).... *The .(dot) character splits the object from its property. For instance, the Columns.Add("Column1").HeaderBackColor = RGB(255,0,0), adds a new column and changes the column's header back color.*

The x-script may uses constant expressions as follow:

- *boolean* expression with possible values as *True* or *False*
- *numeric* expression may starts with 0x which indicates a hexa decimal representation, else it should starts with digit, or +/- followed by a digit, and . is the decimal separator. *Sample: 13 indicates the integer 13, or 12.45 indicates the double expression 12,45*
- *date* expression is delimited by # character in the format #mm/dd/yyyy hh:mm:ss#. *Sample: #31/12/1971# indicates the December 31, 1971*
- *string* expression is delimited by " or ` characters. If using the ` character, please make sure that it is different than ' which allows adding comments inline. *Sample: "text" indicates the string text.*

Also , the template or x-script code may support general functions as follows:

- **Me** *property indicates the original object.*
- **RGB(R,G,B)** *property retrieves an RGB value, where the R, G, B are byte values that indicates the R G B values for the color being specified. For instance, the following code changes the control's background color to red: BackColor = RGB(255,0,0)*
- **LoadPicture(file)** *property loads a picture from a file or from BASE64 encoded strings, and returns a Picture object required by the picture properties.*
- **CreateObject(progID)** *property creates and retrieves a single uninitialized object of*

the class associated with a specified program identifier.

property Gauge.ExtraCaption(Key as Variant, Property as PropertyLayerCaptionEnum) as Variant

Specifies any extra caption on the control.

Type	Description
Key as Variant	A VARIANT expression that specifies the key of the extra caption. You can use any value to identify one extra caption.
Property as PropertyLayerCaptionEnum	A PropertyLayerCaptionEnum expression that specifies the extra caption's property to be changed.
Variant	A VARIANT expression that specifies the value of the extra caption's property.

The control support unlimited HTML captions to be place anywhere on the control or on any layer of the control. The Caption(exLayerCaption) specifies the HTML caption to be shown on the control/layer. The [Images](#) method specifies the list of icons the control can display. The [HTMLPicture](#) adds or replaces a picture in HTML captions. The Caption(exLayerCaptionBackgroundExt) property indicates unlimited options to show any HTML text, images, colors, EBNs, patterns, frames anywhere on the control / layer's background. The caption on the control stay on its position, no matter what layer is moved or rotated, while a caption on a layer gets moved or rotated together with the layer itself.

Any of the following properties can be used to display a HTML caption:

- [Caption](#) property specifies the caption to be shown on the control's foreground.
- ExtraCaption property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

The following screen shot shows a caption on the Top-Left side of the control, and one extra caption to to Bottom-Right side of the control:

The following samples show how you can place caption on the Top-Left side of the control, and one extra caption to to Bottom-Right side of the control:

property Gauge.Font as IFontDisp

Retrieves or sets the control's font.

Type	Description
IFontDisp	A Font object used to paint the items.

Use the Font property to change the control's font . Use the [Refresh](#) method to refresh the control. Use the [BeginUpdate](#) and [EndUpdate](#) method to maintain performance while adding new layers to the control.

Any of the following properties can be used to display a HTML caption:

- [Caption](#) property specifies the caption to be shown on the control's foreground.
- [ExtraCaption](#) property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

The following screen shot shows an extra-caption associated with the layer:

property Gauge.ForeColor as Color

Specifies the control's foreground color.

Type	Description
Color	A Color expression that indicates the control's foreground color.

The ForeColor property specifies the control's foreground color. The [BackColor](#) property specifies the control's background color.

Any of the following properties can be used to display a HTML caption:

- [Caption](#) property specifies the caption to be shown on the control's foreground.
- [ExtraCaption](#) property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

The following screen shot shows an extra-caption associated with the layer:

method Gauge.FormatABC (Expression as String, [A as Variant], [B as Variant], [C as Variant])

Formats the A,B,C values based on the giving expression and returns the result.

Type	Description
Expression as String	A String that defines the expression to be evaluated.
A as Variant	A VARIANT expression that indicates the value of the A keyword.
B as Variant	A VARIANT expression that indicates the value of the B keyword.
C as Variant	A VARIANT expression that indicates the value of the C keyword.

Return	Description
Variant	A VARIANT expression that indicates the result of the evaluation the Expression.

The FormatABC method formats the A,B,C values based on the giving expression and returns the result. The Exontrol's [eXPression](#) component is a syntax-editor that helps you to define, view, edit and evaluate expressions. Using the eXPression component you can easily view or check if the expression you have used is syntactically correct, and you can evaluate what is the result you get giving different values to be tested. The Exontrol's eXPression component can be used as an user-editor, to configure your applications.

For instance:

- "A + B + C", adds / concatenates the values of the A, B and C
- "value MIN 0 MAX 99", limits the value between 0 and 99
- "value format ` `", formats the value with two decimals, according to the control's panel setting
- "date(`now`)" returns the current time as double

The Expression of the FormatABC method supports the following keywords, constants, operators and functions:

- **A** or **value** keyword, indicates a variable A whose value is giving by the A parameter
- **B** keyword, indicates a variable B whose value is giving by the B parameter
- **C** keyword, indicates a variable C whose value is giving by the C parameter

The constants are (DPI-Aware components):

- **dpi** (DPI constant), specifies the current DPI setting. and it indicates the minimum

value between **dpix** and **dpiy** constants. For instance, if current DPI setting is 100%, the dpi constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpi returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%

- **dpix** (DPIX constant), specifies the current DPI setting on x-scale. For instance, if current DPI setting is 100%, the dpix constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpix returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%
- **dpiy** (DPIY constant), specifies the current DPI setting on y-scale. For instance, if current DPI setting is 100%, the dpiy constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpiy returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%

The supported binary arithmetic operators are:

- * (multiplication operator), priority 5
- / (divide operator), priority 5
- **mod** (remainder operator), priority 5
- + (addition operator), priority 4 (concatenates two strings, if one of the operands is of string type)
- - (subtraction operator), priority 4

The supported unary boolean operators are:

- **not** (not operator), priority 3 (high priority)

The supported binary boolean operators are:

- **or** (or operator), priority 2
- **and** (and operator), priority 1

The supported binary boolean operators, all these with the same priority 0, are :

- < (less operator)
- <= (less or equal operator)
- = (equal operator)
- != (not equal operator)
- >= (greater or equal operator)
- > (greater operator)

The supported binary range operators, all these with the same priority 5, are :

- **MIN** (min operator), indicates the minimum value, so a **MIN** b returns the value of a, if it is less than b, else it returns b. For instance, the expression value MIN 10 returns

always a value greater than 10.

- **MAX** (max operator), indicates the maximum value, so a **MAX** b returns the value of a, if it is greater than b, else it returns b. For instance, the expression value MAX 100 returns always a value less than 100.

The supported binary operators, all these with the same priority 0, are :

- **:= (Store operator)**, stores the result of expression to variable. The syntax for := operator is

variable := expression

where variable is a integer between 0 and 9. You can use the := operator to restore any stored variable (please make the difference between := and =:). For instance, (0:=dbl(value)) = 0 ? "zero" : =:0, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the := and =: are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

- **=: (Restore operator)**, restores the giving variable (previously saved using the store operator). The syntax for =: operator is

=: variable

where variable is a integer between 0 and 9. You can use the := operator to store the value of any expression (please make the difference between := and =:). For instance, (0:=dbl(value)) = 0 ? "zero" : =:0, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the := and =: are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

The supported ternary operators, all these with the same priority 0, are :

- **? (Immediate If operator)**, returns and executes one of two expressions, depending on the evaluation of an expression. The syntax for ? operator is

expression ? true_part : false_part

, while it executes and returns the true_part if the expression is true, else it executes and returns the false_part. For instance, the %0 = 1 ? 'One' : (%0 = 2 ? 'Two' : 'not found') returns 'One' if the value is 1, 'Two' if the value is 2, and 'not found' for any other value. A n-ary equivalent operation is the case() statement, which is available in newer versions of the component.

The supported *n*-ary operators are (with priority 5):

- **array** (*at operator*), returns the element from an array giving its index (0 base). The *array* operator returns empty if the element is found, else the associated element in the collection if it is found. The syntax for *array* operator is

expression array (c1,c2,c3,...cn)

, where the c1, c2, ... are constant elements. The constant elements could be numeric, date or string expressions. For instance the *month(value)-1 array* ('J','F','M','A','M','Jun','J','A','S','O','N','D') is equivalent with *month(value)-1 case* (default:"; 0:'J';1:'F';2:'M';3:'A';4:'M';5:'Jun';6:'J';7:'A';8:'S';9:'O';10:'N';11:'D').

- **in** (*include operator*), specifies whether an element is found in a set of constant elements. The *in* operator returns -1 (True) if the element is found, else 0 (false) is retrieved. The syntax for *in* operator is

expression in (c1,c2,c3,...cn)

, where the c1, c2, ... are constant elements. The constant elements could be numeric, date or string expressions. For instance the *value in (11,22,33,44,13)* is equivalent with (*expression = 11*) or (*expression = 22*) or (*expression = 33*) or (*expression = 44*) or (*expression = 13*). The *in* operator is not a time consuming as the equivalent *or* version is, so when you have large number of constant elements it is recommended using the *in* operator. Shortly, if the collection of elements has 1000 elements the *in* operator could take up to 8 operations in order to find if an element fits the set, else if the *or* statement is used, it could take up to 1000 operations to check, so by far, the *in* operator could save time on finding elements within a collection.

- **switch** (*switch operator*), returns the value being found in the collection, or a predefined value if the element is not found (default). The syntax for *switch* operator is

expression switch (default,c1,c2,c3,...,cn)

, where the c1, c2, ... are constant elements, and the default is a constant element being returned when the element is not found in the collection. The constant elements could be numeric, date or string expressions. The equivalent syntax is "%0 = c 1 ? c 1 : (%0 = c 2 ? c 2 : (... ? . : default))". The *switch* operator is very similar with the *in* operator excepts that the first element in the switch is always returned by the statement if the element is not found, while the returned value is the value itself instead -1. For instance, the *%0 switch ('not found',1,4,7,9,11)* gets 1, 4, 7, 9 or 11, or 'not found' for any other value. As the *in* operator the *switch* operator uses binary searches for fitting the element, so it is quicker than *if* (immediate if operator) alternative.

- **case()** (case operator) returns and executes one of n expressions, depending on the evaluation of the expression (IIF - immediate IF operator is a binary case() operator). The syntax for case() operator is:

expression case ([default : default_expression ;] c1 : expression1 ; c2 : expression2 ; c3 : expression3 ;....)

If the default part is missing, the case() operator returns the value of the expression if it is not found in the collection of cases (c1, c2, ...). For instance, if the value of expression is not any of c1, c2, the default_expression is executed and returned. If the value of the expression is c1, then the case() operator executes and returns the expression1. The default, c1, c2, c3, ... must be constant elements as numbers, dates or strings. For instance, the *date(shortdate(value)) case (default:0 ; #1/1/2002#:1 ; #2/1/2002#:1; #4/1/2002#:1; #5/1/2002#:1)* indicates that only #1/1/2002#, #2/1/2002#, #4/1/2002# and #5/1/2002# dates returns 1, since the others returns 0. For instance the following sample specifies the hour being non-working for specified dates: *date(shortdate(value)) case(default:0;#4/1/2009# : hour(value) >= 6 and hour(value) <= 12 ; #4/5/2009# : hour(value) >= 7 and hour(value) <= 10 or hour(value) in(15,16,18,22); #5/1/2009# : hour(value) <= 8)* statement indicates the working hours for dates as follows:

- #4/1/2009#, from hours 06:00 AM to 12:00 PM
- #4/5/2009#, from hours 07:00 AM to 10:00 AM and hours 03:00PM, 04:00PM, 06:00PM and 10:00PM
- #5/1/2009#, from hours 12:00 AM to 08:00 AM

The *in*, *switch* and *case()* use binary search to look for elements so they are faster then using *iif* and *or* expressions. Obviously, the priority of the operations inside the expression is determined by () parenthesis and the priority for each operator.

The supported conversion unary operators are:

- **type** (unary operator) retrieves the type of the object. For instance *type(%1) = 8* specifies the cells (on the column 1) that contains string values.

Here's few predefined types:

- 0 - empty (not initialized)
- 1 - null
- 2 - short
- 3 - long
- 4 - float
- 5 - double
- 6 - currency

- 7 - date
- 8 - string
- 9 - object
- 10 - error
- 11 - boolean
- 12 - variant
- 13 - any
- 14 - decimal
- 16 - char
- 17 - byte
- 18 - unsigned short
- 19 - unsigned long
- 20 - long on 64 bits
- 21 - unsigned long on 64 bites
- **str** (unary operator) converts the expression to a string. The str operator converts the expression to a string. For instance, the *str(-12.54)* returns the string "-12.54".
- **dbl** (unary operator) converts the expression to a number. The dbl operator converts the expression to a number. For instance, the *dbl("12.54")* returns 12.54
- **date** (unary operator) converts the expression to a date, based on your regional settings. For instance, the *date(`)* gets the current date (no time included), the *date(`now`)* gets the current date-time, while the *date("01/01/2001")* returns #1/1/2001#
- **dateS** (unary operator) converts the string expression to a date using the format MM/DD/YYYY HH:MM:SS. For instance, the *dateS("01/01/2001 14:00:00")* returns #1/1/2001 14:00:00#

Other known operators for numbers are:

- **int** (unary operator) retrieves the integer part of the number. For instance, the *int(12.54)* returns 12
- **round** (unary operator) rounds the number ie 1.2 gets 1, since 1.8 gets 2. For instance, the *round(12.54)* returns 13
- **floor** (unary operator) returns the largest number with no fraction part that is not greater than the value of its argument. For instance, the *floor(12.54)* returns 12
- **abs** (unary operator) retrieves the absolute part of the number ie -1 gets 1, 2 gets 2. For instance, the *abs(-12.54)* returns 12.54
- **sin** (unary operator) returns the sine of an angle of x radians. For instance, the *sin(3.14)* returns 0.001593.
- **cos** (unary operator) returns the cosine of an angle of x radians. For instance, the *cos(3.14)* returns -0.999999.
- **asin** (unary operator) returns the principal value of the arc sine of x, expressed in radians. For instance, the *2*asin(1)* returns the value of PI.

- **acos** (unary operator) returns the principal value of the arc cosine of x, expressed in radians. For instance, the `2*acos(0)` returns the value of PI
- **sqrt** (unary operator) returns the square root of x. For instance, the `sqrt(81)` returns 9.
- **currency** (unary operator) formats the giving number as a currency string, as indicated by the control panel. For instance, `currency(value)` displays the value using the current format for the currency ie, 1000 gets displayed as \$1,000.00, for US format.
- value **format** 'flags' (binary operator) formats the value with specified flags. If flags is empty, the number is displayed as shown in the field "Number" in the "Regional and Language Options" from the Control Panel. For instance the `1000 format "` displays 1,000.00 for English format, while 1.000,00 is displayed for German format. `1000 format '2|.|3|,'` will always displays 1,000.00 no matter of settings in the control panel. If formatting the number fails for some invalid parameter, the value is displayed with no formatting.

The ' flags' for format operator is a list of values separated by | character such as '*NumDigits|DecimalSep|Grouping|ThousandSep|NegativeOrder|LeadingZero*' with the following meanings:

- *NumDigits* - specifies the number of fractional digits, If the flag is missing, the field "No. of digits after decimal" from "Regional and Language Options" is using.
- *DecimalSep* - specifies the decimal separator. If the flag is missing, the field "Decimal symbol" from "Regional and Language Options" is using.
- *Grouping* - indicates the number of digits in each group of numbers to the left of the decimal separator. Values in the range 0 through 9 and 32 are valid. The most significant grouping digit indicates the number of digits in the least significant group immediately to the left of the decimal separator. Each subsequent grouping digit indicates the next significant group of digits to the left of the previous group. If the last value supplied is not 0, the remaining groups repeat the last group. Typical examples of settings for this member are: 0 to group digits as in 123456789.00; 3 to group digits as in 123,456,789.00; and 32 to group digits as in 12,34,56,789.00. If the flag is missing, the field "Digit grouping" from "Regional and Language Options" indicates the grouping flag.
- *ThousandSep* - specifies the thousand separator. If the flag is missing, the field "Digit grouping symbol" from "Regional and Language Options" is using.
- *NegativeOrder* - indicates the negative number mode. If the flag is missing, the field "Negative number format" from "Regional and Language Options" is using. The valid values are 0, 1, 2, 3 and 4 with the following meanings:
 - 0 - Left parenthesis, number, right parenthesis; for example, (1.1)
 - 1 - Negative sign, number; for example, -1.1
 - 2 - Negative sign, space, number; for example, - 1.1
 - 3 - Number, negative sign; for example, 1.1-
 - 4 - Number, space, negative sign; for example, 1.1 -
- *LeadingZero* - indicates if leading zeros should be used in decimal fields. If the

flag is missing, the field "Display leading zeros" from "Regional and Language Options" is using. The valid values are 0, 1

Other known operators for strings are:

- **len** (unary operator) retrieves the number of characters in the string. For instance, the *len("Mihai")* returns 5.
- **lower** (unary operator) returns a string expression in lowercase letters. For instance, the *lower("MIHAI")* returns "mihai"
- **upper** (unary operator) returns a string expression in uppercase letters. For instance, the *upper("mihai")* returns "MIHAI"
- **proper** (unary operator) returns from a character expression a string capitalized as appropriate for proper names. For instance, the *proper("mihai")* returns "Mihai"
- **ltrim** (unary operator) removes spaces on the left side of a string. For instance, the *ltrim(" mihai")* returns "mihai"
- **rtrim** (unary operator) removes spaces on the right side of a string. For instance, the *rtrim("mihai ")* returns "mihai"
- **trim** (unary operator) removes spaces on both sides of a string. For instance, the *trim(" mihai ")* returns "mihai"
- **reverse** (unary operator) reverses the order of the characters in the string a. For instance, the *reverse("Mihai")* returns "iahIM"
- **startswith** (binary operator) specifies whether a string starts with specified string (0 if not found, -1 if found). For instance *"Mihai" startwith "Mi"* returns -1
- **endwith** (binary operator) specifies whether a string ends with specified string (0 if not found, -1 if found). For instance *"Mihai" endwith "ai"* returns -1
- **contains** (binary operator) specifies whether a string contains another specified string (0 if not found, -1 if found). For instance *"Mihai" contains "ha"* returns -1
- **left** (binary operator) retrieves the left part of the string. For instance *"Mihai" left 2* returns "Mi".
- **right** (binary operator) retrieves the right part of the string. For instance *"Mihai" right 2* returns "ai"
- **a lfind b** (binary operator) The a lfind b (binary operator) searches the first occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" lfind "C"* returns 2
- **a rfind b** (binary operator) The a rfind b (binary operator) searches the last occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" rfind "C"* returns 5.
- **a mid b** (binary operator) retrieves the middle part of the string a starting from b (1 means first position, and so on). For instance *"Mihai" mid 2* returns "ihai"
- **a count b** (binary operator) retrieves the number of occurrences of the b in a. For instance *"Mihai" count "i"* returns 2.
- **a replace b with c** (double binary operator) replaces in a the b with c, and gets the

result. For instance, the *"Mihai"* replace *"i" with ""* returns "Mha" string, as it replaces all "i" with nothing.

- a **split** b, splits the a using the separator b, and returns an array. For instance, the *weekday(value) array 'Sun Mon Thu Wed Thu Fri Sat' split ' '* gets the weekday as string. This operator can be used with the array.

Other known operators for dates are:

- **time** (unary operator) retrieves the time of the date in string format, as specified in the control's panel. For instance, the *time(#1/1/2001 13:00#)* returns "1:00:00 PM"
- **timeF** (unary operator) retrieves the time of the date in string format, as "HH:MM:SS". For instance, the *timeF(#1/1/2001 13:00#)* returns "13:00:00"
- **shortdate** (unary operator) formats a date as a date string using the short date format, as specified in the control's panel. For instance, the *shortdate(#1/1/2001 13:00#)* returns "1/1/2001"
- **shortdateF** (unary operator) formats a date as a date string using the "MM/DD/YYYY" format. For instance, the *shortdateF(#1/1/2001 13:00#)* returns "01/01/2001"
- **dateF** (unary operator) converts the date expression to a string expression in "MM/DD/YYYY HH:MM:SS" format. For instance, the *dateF(#01/01/2001 14:00:00#)* returns #01/01/2001 14:00:00#
- **longdate** (unary operator) formats a date as a date string using the long date format, as specified in the control's panel. For instance, the *longdate(#1/1/2001 13:00#)* returns "Monday, January 01, 2001"
- **year** (unary operator) retrieves the year of the date (100,...,9999). For instance, the *year(#12/31/1971 13:14:15#)* returns 1971
- **month** (unary operator) retrieves the month of the date (1, 2,...,12). For instance, the *month(#12/31/1971 13:14:15#)* returns 12.
- **day** (unary operator) retrieves the day of the date (1, 2,...,31). For instance, the *day(#12/31/1971 13:14:15#)* returns 31
- **yearday** (unary operator) retrieves the number of the day in the year, or the days since January 1st (0, 1,...,365). For instance, the *yearday(#12/31/1971 13:14:15#)* returns 365
- **weekday** (unary operator) retrieves the number of days since Sunday (0 - Sunday, 1 - Monday,..., 6 - Saturday). For instance, the *weekday(#12/31/1971 13:14:15#)* returns 5.
- **hour** (unary operator) retrieves the hour of the date (0, 1, ..., 23). For instance, the *hour(#12/31/1971 13:14:15#)* returns 13
- **min** (unary operator) retrieves the minute of the date (0, 1, ..., 59). For instance, the *min(#12/31/1971 13:14:15#)* returns 14
- **sec** (unary operator) retrieves the second of the date (0, 1, ..., 59). For instance, the *sec(#12/31/1971 13:14:15#)* returns 15

property Gauge.FormatAnchor(New as Boolean) as String

Specifies the visual effect for anchor elements in HTML captions.

Type	Description
New as Boolean	A Boolean expression that indicates whether to specify the anchors never clicked or anchors being clicked.
String	A String expression that indicates the HTMLformat to apply to anchor elements.

By default, the FormatAnchor(**True**) property is "<u><fgcolor=0000FF>#" that indicates that the anchor elements (that were never clicked) are underlined and shown in light blue. Also, the FormatAnchor(**False**) property is "<u><fgcolor=000080>#" that indicates that the anchor elements are underlined and shown in dark blue. The visual effect is applied to the anchor elements, if the FormatAnchor property is not empty. For instance, if you want to do not show with a new effect the clicked anchor elements, you can use the FormatAnchor(**False**) = "", that means that the clicked or not-clicked anchors are shown with the same effect that's specified by FormatAnchor(**True**). An anchor is a piece of text or some other object (for example an image) which marks the beginning and/or the end of a hypertext link. The <a> element is used to mark that piece of text (or inline image), and to give its hypertextual relationship to other documents. The control fires the [AnchorClick](#) event to notify that the user clicks an anchor element. This event is fired only if prior clicking the control it shows the hand cursor. The AnchorClick event carries the identifier of the anchor, as well as application options that you can specify in the anchor element. The hand cursor is shown when the user hovers the mouse on the anchor elements.

method Gauge.FreezeEvents (Freeze as Boolean)

Prevents the control to fire any event.

Type	Description
Freeze as Boolean	A Boolean expression that specifies whether the control' events are froze or unfroze

The FreezeEvents(True) method freezes the control's events until the FreezeEvents(False) method is called. You can use the FreezeEvents method to enable / disable the control's events.

property Gauge.HTMLPicture(Key as String) as Variant

Adds or replaces a picture in HTML captions.

Type	Description
Key as String	A String expression that indicates the key of the picture being added or replaced. If the Key property is Empty string, the entire collection of pictures is cleared.
Variant	<p>The HTMLPicture specifies the picture being associated to a key. It can be one of the followings:</p> <ul style="list-style-type: none">• a string expression that indicates the path to the picture file, being loaded.• a string expression that indicates the base64 encoded string that holds a picture object, Use the Exontrol's ExImages Tool to save your picture as base64 encoded format.• A Picture object that indicates the picture being added or replaced. (A Picture object implements IPicture interface), <p>If empty, the picture being associated to a key is removed. If the key already exists the new picture is replaced. If the key is not empty, and it doesn't not exist a new picture is added.</p>

The HTMLPicture property handles a collection of custom size picture being displayed in the HTML captions, using the tags. By default, the HTMLPicture collection is empty. Use the HTMLPicture property to add new pictures to be used in HTML captions. For instance, the HTMLPicture("pic1") = "c:\winnt\zapotec.bmp", loads the zapotec picture and associates the pic1 key to it. Any "pic1" sequence in HTML captions, displays the pic1 picture. On return, the HTMLPicture property retrieves a Picture object (this implements the IPictureDisp interface).

The following sample shows how to put a custom size picture in the column's header:

```
<CONTROL>.HTMLPicture("pic1") = "c:/temp/editors.gif"
<CONTROL>.HTMLPicture("pic2") = "c:/temp/editpaste.gif"

<COLUMN1>.HTMLCaption = "A <img>pic1</img>"
<COLUMN2>.HTMLCaption = "B <img>pic2</img>"
<COLUMN3>.HTMLCaption = "A <img>pic1</img> + B <img>pic2</img>"
```

property Gauge.hWnd as Long

Retrieves the control's window handle.

Type	Description
Long	A long expression that indicates the control's window handle.

Use the hWnd property to get the control's main window handle. The Microsoft Windows operating environment identifies each form and control in an application by assigning it a handle, or hWnd. The hWnd property is used with Windows API calls. Many Windows operating environment functions require the hWnd of the active window as an argument.

method Gauge.Images (Handle as Variant)

Sets a runtime the control's image tree.

Type	Description
Handle as Variant	<p>The Handle parameter can be:</p> <ul style="list-style-type: none">• A string expression that specifies the ICO file to add. The ICO file format is an image file format for computer icons in Microsoft Windows. ICO files contain one or more small images at multiple sizes and color depths, such that they may be scaled appropriately. For instance, Images("c:\temp\copy.ico") method adds the sync.ico file to the control's Images collection (<i>string, loads the icon using its path</i>)• A string expression that indicates the BASE64 encoded string that holds the icons list. Use the Exontrol's ExImages tool to save/load your icons as BASE64 encoded format. In this case the string may begin with "gBJJ..." (<i>string, loads icons using base64 encoded string</i>)• A reference to a Microsoft ImageList control (mscomctl.ocx, MSComctlLib.ImageList type) that holds the icons to add (<i>object, loads icons from a Microsoft ImageList control</i>)• A reference to a Picture (IPictureDisp implementation) that holds the icon to add. For instance, the VB's LoadPicture (Function LoadPicture([FileName], [Size], [ColorDepth], [X], [Y]) As IPictureDisp) or LoadResPicture (Function LoadResPicture(id, restype As Integer) As IPictureDisp) returns a picture object (<i>object, loads icon from a Picture object</i>)• A long expression that identifies a handle to an Image List Control (the Handle should be of HIMAGELIST type). On 64-bit platforms, the Handle parameter must be a Variant of LongLong / LONG_PTR data type (signed 64-bit (8-byte) integers), saved under lVal field, as VT_I8 type. The LONGLONG / LONG_PTR is __int64, a 64-bit integer. For instance, in C++ you can use as Images(COleVariant(LONG_PTR)hImageList)) or Images(COleVariant(LONGLONG)hImageList)), where hImageList is of

HIMAGELIST type. The GetSafeHandle() method of the CImageList gets the HIMAGELIST handle (long, loads icon from HIMAGELIST type)

The user can add images at design time, by drag and drop files to combo's image holder. The [ImageSize](#) property defines the size (width/height) of the icons within the control's Images collection. Use the [Replacelcon](#) method to add, remove or clear icons in the control's images collection.

property Gauge.ImageSize as Long

Retrieves or sets the size of icons the control displays..

Type	Description
Long	A long expression that defines the size of icons the control displays.

By default, the ImageSize property is 16 (pixels). The ImageSize property specifies the size of icons being loaded using the [Images](#) method. The control's Images collection is cleared if the ImageSize property is changed, so it is recommended to set the ImageSize property before calling the Images method. The ImageSize property defines the size (width/height) of the icons within the control's Images collection. For instance, if the ICO file to load includes different types the one closest with the size specified by ImageSize property is loaded by Images method. The ImageSize property does NOT change the height for the control's font.

property Gauge.LayerAutoSize as Long

Specifies the index of the layer that determines the size to display all layers.

Type	Description
Long	A Long expression that indicates the index of the layer that determines the size to display all layers

By default, the LayerAutoSize property is 0, which indicates that the size of the entire view is defined by the size of the first layer. The size of the layer is determined by its picture ([Picture](#) property). Shortly, the LayerAutoSize resizes all layers based on the picture of the first layer.

For instance, you can use the LayerAutoSize property to:

- stretches all the layers to the control's view, if the LayerAutoSize property is -1 (or any other value that's not an index in the Layers collection)
- resizes all layers relative to a specified layer and its background picture
- resizes all layers to a specified layer, whose [Width](#) and [Height](#) properties specify the size of the view.

The following properties determine the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [DefaultOffsetX](#), gets or sets a value that indicates the default x-offset of the layer.
- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetXValid](#), validates the x-offset value of the layer.
- [Value](#) and [ValueToOffsetX](#) specifies the expression to convert the value to x-offset.
- [DefaultOffsetY](#), gets or sets a value that indicates the default y-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.
- [OffsetYValid](#), validates the y-offset value of the layer.
- [Value](#) and [ValueToOffsetY](#) specifies the expression to convert the value to y-offset.

The following properties can be used to move /resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

The following samples show how you can resize the control's view to 164 x 164 pixels, by adding a new hidden layer called "autosize":

VBA (MS Access, Excell...)

```
With Gauge1
    .BeginUpdate
    .PicturesPath = "C:\Program
Files\Exontrol\ExGauge\Sample\Design\Circular\Knob"
    .PicturesName = "`Layer` + int(value + 1) + `.png`"
    .Layers.Count = 10
    With .Layers.Add("autosize")
        .Visible = False
        .Width = 164
        .Height = 164
    End With
    .LayerAutoSize = .Layers.Item("autosize").Index
    .EndUpdate
End With
```

VB6

```
With Gauge1
    .BeginUpdate
    .PicturesPath = "C:\Program
Files\Exontrol\ExGauge\Sample\Design\Circular\Knob"
    .PicturesName = "`Layer` + int(value + 1) + `.png`"
```

```

.Layers.Count = 10
With .Layers.Add("autosize")
    .Visible = False
    .Width = 164
    .Height = 164
End With
.LayerAutoSize = .Layers.Item("autosize").Index
.EndUpdate
End With

```

VB.NET

```

With Exgauge1
    .BeginUpdate()
    .PicturesPath = "C:\Program
Files\Exontrol\ExGauge\Sample\Design\Circular\Knob"
    .PicturesName = ""Layer` + int(value + 1) + `.png""
    .Layers.Count = 10
    With .Layers.Add("autosize")
        .Visible = False
        .Width = 164
        .Height = 164
    End With
    .LayerAutoSize = .Layers.Item("autosize").Index
    .EndUpdate()
End With

```

VB.NET for /COM

```

With AxGauge1
    .BeginUpdate()
    .PicturesPath = "C:\Program
Files\Exontrol\ExGauge\Sample\Design\Circular\Knob"
    .PicturesName = ""Layer` + int(value + 1) + `.png""
    .Layers.Count = 10
    With .Layers.Add("autosize")
        .Visible = False
        .Width = 164

```

```

        .Height = 164
    End With
    .LayerAutoSize = .Layers.Item("autosize").Index
    .EndUpdate()
End With

```

C++

```

/*

```

property Gauge.LayerClipTo as Long

Specifies the index of the layer that clips the entire control to.

Type	Description
Long	A Long expression that specifies the index of the layer that clips the entire control to.

By default, the LayerClipTo property is -1, which indicates that it has no effect. The LayerClipTo property specifies the index of the layer that clips the entire control to. The [LayerClipToAlpha](#) property returns or sets a value that indicates the value of the alpha channel to be included in the LayerClipTo region. The [LayerClipToParent](#) property indicates if the LayerClipTo method clips the control itself, parent or the owner of the control. The [AllowMoveOnClick](#) property allows moving the window that contains the control to a new position, as you would do by clicking the form's title/caption. The [LayerUpdate](#) property helps you to create a smooth widget on the screen or form.

"I would like to put the control on a form, then make the form transparent so the control appears on the desktop with just the images contained in the layers visible. For example, take a clock example and make the control background and the form transparent, and you have a working clock widget."

The control support transparent form, or in other words, displaying the control's itself without its form behind. In order to make your eXGauge control to display a widget, (no form behind or form transparent), you need to use the following properties:

- **LayerClipTo** property of the control, specifies the index of the layer that clips the entire control to. By default, the LayerClipTo property is -1, which indicates that no clipping is supported. So, one of the layers that composes your widget must be specified as the widget's background, and so, the entire view of the control is clipped to region defined by the clipping layer (LayerClipTo). The LayerClipTo property may refer to any layer, visible or hidden, which includes a picture or a clipping object (Clip property).
- [Layer.LayerClipToAlpha](#) property of the Layer object, returns or sets a value that indicates the value of the alpha channel to be included in the LayerClipTo region. By default, the LayerClipToAlpha property is 0, which indicates that only pixels of the layer that has 0 on the alpha channel (transparent pixels) defines the transparent region, and so the clipping region. In other words, the value from 0 to LayerClipToAlpha defines transparent pixels, and the rest defines the opaque pixels to be included in the clipping region. So based on the layer's picture, you can change the LayerClipToAlpha property for a better look of your widget.
- [LayerClipToParent](#) property of the control, indicates if the LayerClipTo method clips the control itself, parent or the owner of the control. By default, the LayerClipToParent

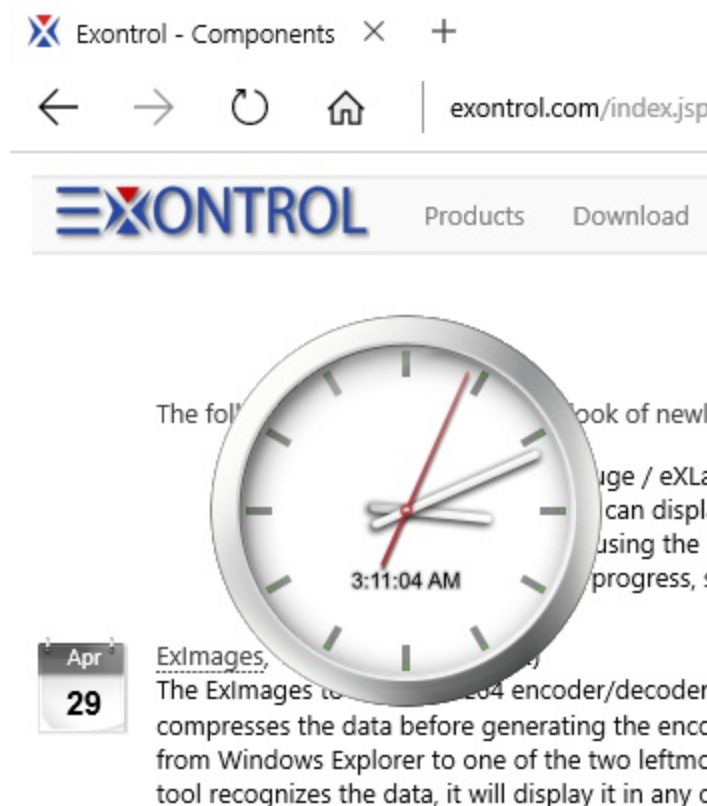

property is `exLayerUpdateControl`, which indicates that the control's itself is clipped relative to its form that hosts it. Change the `LayerClipToParent` property to `exLayerUpdateScreen`, or `exLayerUpdateParent`, and so the clipping region is applied to its form/dialog/parent window.

The following VB sample defines the control as a widget:

```
With Gauge1
    .LayerClipTo = 0
    .LayerClipToParent = exLayerUpdateScreen
End With
```

The sample defines the layer with the Index 0, as being the clipping layer. The setup installs the `C:\Program Files\Exontrol\ExGauge\Sample\VB\Clock-Widget-Region` that shows all these working.

The following screen shot shows the control on a transparent form:

The following screen shot shows the control on an opaque form:

tool recognizes the data, it will display it in any c

property Gauge.LayerClipToParent as LayerUpdateEnum

Indicates if the LayerClipTo method clips the control itself, parent or the owner of the control.

Type	Description
LayerUpdateEnum	A LayerUpdateEnum expression that specifies the

By default, the LayerClipToParent property is exLayerUpdateControl, which indicates that the control's itself is clipped relative to its form that hosts it. Change the LayerClipToParent property to exLayerUpdateScreen, or exLayerUpdateParent, and so the clipping region is applied to its form/dialog/parent window. The [LayerClipTo](#) property specifies the index of the layer that clips the entire control to. The [LayerClipToAlpha](#) property returns or sets a value that indicates the value of the alpha channel to be included in the LayerClipTo region.

"I would like to put the control on a form, then make the form transparent so the control appears on the desktop with just the images contained in the layers visible. For example, take a clock example and make the control background and the form transparent, and you have a working clock widget."

The control support transparent form, or in other words, displaying the control's itself without its form behind. In order to make your eXGauge control to display a widget, (no form behind or form transparent), you need to use the following properties:

- **LayerClipTo** property of the control, specifies the index of the layer that clips the entire control to. By default, the LayerClipTo property is -1, which indicates that no clipping is supported. So, one of the layers that composes your widget must be specified as the widget's background, and so, the entire view of the control is clipped to region defined by the clipping layer (LayerClipTo). The LayerClipTo property may refer to any layer, visible or hidden, which includes a picture or a clipping object (Clip property).
- [Layer.LayerClipToAlpha](#) property of the Layer object, returns or sets a value that indicates the value of the alpha channel to be included in the LayerClipTo region. By default, the LayerClipToAlpha property is 0, which indicates that only pixels of the layer that has 0 on the alpha channel (transparent pixels) defines the transparent region, and so the clipping region. In other words, the value from 0 to LayerClipToAlpha defines transparent pixels, and the rest defines the opaque pixels to be included in the clipping region. tool recognizes the data, it will display it in any c

property Gauge.LayerDragAny as Long

Specifies the index of the layer to drag (rotate or move) once the user clicks anywhere on the control.

Type	Description
Long	A long expression that specifies the index of the layer to drag (rotate or move) once the user clicks anywhere on the control.

By default, the LayerDragAny property is -1, which indicates that has no effect. The LayerDragAny property specifies the index of the layer to drag (rotate or move) once the user clicks anywhere on the control. For instance, if the LayerDragAny property is 0, it means that the layer with the index-0 is always dragging no matter where the cursor is.

property Gauge.LayerFromPoint (X as OLE_XPOS_PIXELS, Y as OLE_YPOS_PIXELS) as Long

Retrieves the index of the layer from the point (only visible and selectable objects are included).

Type	Description
X as OLE_XPOS_PIXELS	A long expression that specifies the x-position in client coordinate to get the layer from.
Y as OLE_YPOS_PIXELS	A long expression that specifies the y-position in client coordinate to get the layer from.
Long	A Long expression that specifies the index of the layer from the cursor, or -1 if not found.

The LayerFromPoint property retrieves the layer from point that's visible and selectable. The [Visible](#) property shows or hides a specific layer (visible). The [Selectable](#) property returns or sets a value that indicates whether the layer is selectable. The [Item](#) property accesses the Layer object giving its index. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (draggable). Use the [ShowToolTip](#) method to display a custom tooltip. The [ToolTip](#) / [ToolTipTitle](#) property indicates the layer's tooltip. The [MouseMove](#) event is generated continually as the mouse pointer moves across objects.

property Gauge.LayerOfValue as Long

Specifies the index of the layer whose value represents the control's Value property.

Type	Description
Long	A Long expression that specifies the index of the layer whose Value represents the control's Value property, or -1 to which indicates that last visible layer with OnDrag property set.

By default, the LayerOfValue property is -1, which indicates that the last visible layer whose [OnDrag](#) property is not exDoNothing, is the layer that specifies the control's value. The LayerOfValue property specifies the index of the layer whose value represents the control's Value property. The layer's [Value](#) could indicate its offset or its rotation angle, based on the [OnDrag](#) property. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (draggable). Use the [Value](#) property of the Clip object to associate a value with the layer's clipping region. Each layer can associate a value with it, while the control's Value property can be associated through the LayerOfValue property with the value of one of the layers within the control.

For instance:

- the control displays a clock, the value could be the current-time
- the control shows a switch, so the value could indicate the state of the switch
- the control shows a thermometer, so the value could be the current temperature
- the control displays a gauge, so the value could be the value on the gauge pointed by the needle

The [Change](#) event occurs when the layer's Value property is changed. During the Change event, you can change values of other layers as well. For instance, if the second-hand of the clock is rotated, you can rotate the hour and the minute-hands of the clock as well. The [DragStart](#) / [Drag](#) / [DragEnd](#) events notify your application when a layer is dragged. *You can call DragInfo.Debug = -1 during the [DragStart](#) event to display debugging information like current movement, rotation angle when drag operation is performed.*

The Value property indicates the **value** keyword in the following properties:

- [ValueToOffsetX](#), Specifies the expression to convert the value to x-offset. The layer's [OffsetX](#) property is the result of evaluating the [ValueToOffsetX](#) expression, while the [OnDrag](#) property is **exDoMove**. The [OffsetToValue](#) converts the current offset to a value.
- [ValueToOffsetY](#), Specifies the expression to convert the value to y-offset. The layer's [OffsetY](#) property is the result of evaluating the [ValueToOffsetY](#) expression, while the [OnDrag](#) property is **exDoMove**. The [OffsetToValue](#) converts the current offset to a

value.

- [ValueToRotateAngle](#), Specifies the expression to convert the value to rotating angle. The layer's [RotateAngle](#) property is the result of evaluating the [ValueToRotateAngle](#) expression, while the [OnDrag](#) property is **exDoRotate** or **exDoRotamove**. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The Value property works in association with the layer's [OnDrag](#) property like follows:

- If the [OnDrag](#) property is **exDoMove**, evaluating the [ValueToOffsetX](#) property indicates the layer's [OffsetX](#) property.
- If the [OnDrag](#) property is **exDoMove**, evaluating the [ValueToOffsetY](#) property indicates the layer's [OffsetY](#) property.
- If the [OnDrag](#) property is **exDoRotate** or **exDoRotamove**, evaluating the [ValueToRotateAngle](#) property indicates the layer's [RotateAngle](#) property.

property Gauge.Layers as Layers

Returns the Layers collection.

Type	Description
Layers	A Layers collection of Layer objects.

The Layers property gives access to the control's Layers collection. Any layer can display unlimited opaque / transparent graphics, HTML text, can be visible, selectable, draggable and so on. Any layer can change its position in the layers collection as well. The Layer can change its brightness, contrast, grayscale or transparency as well.

The following screen shot shows a control composed by two pictures:
"Guage_Background.png" and "Guage_Needle.png" from the "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Guage" folder

The following picture shows how layers "background" and "needle" composes the control's view

The following properties can be used to add / remove layers within the control:

- [Count](#) property, adds / removes layers to / from the control
- [Add](#) method, adds a new layer to the control.

The following properties can be used to access Layer objects in the control:

- [Item](#) property, gives the Layer object based on its index / key. The [Count](#) property specifies the number of layers within the control
- [VisibleItem](#) property, gives the visible layer based on its position. The [VisibleCount](#) property indicates the number of visible layers within the control. The [Visible](#) property shows or hides the layer. The [ShowLayers](#) property indicates the only layers to be shown on the control.

property Gauge.LayerUpdate as LayerUpdateEnum

Specifies where the control updates its content.

Type	Description
LayerUpdateEnum	A LayerUpdateEnum expression that specifies where the control updates its content.

By default, the LayerUpdate property property is exLayerUpdateControl, which indicates that the control's content is shown on the control itself (no effect). The LayerUpdate property indicates where the control's content is updated. The control support transparent form, or in other words, displaying the control's itself without its form behind. The [AllowMoveOnClick](#) property allows moving the window that contains the control to a new position, as you would do by clicking the form's title/caption. The [LayerClipTo](#) property specifies the index of the layer that clips the entire control to.

In order to make your eXGauge control to display a widget, (no form behind or form transparent), you need to use the following properties:

- Change the LayerUpdate property to **exLayerUpdateScreen**, so the entire control is shown individually on the screen, with no form behind.

In order to make your eXGauge library to display a transparent-control inside your form/dialog/window/child, you need to use the following properties:

- Change the LayerUpdate property to **exLayerUpdateParent**, so the control itself (with no nackground) is shown on the form/dialog/parent.
- You need to add **<supportedOS Id="{4a2f28e3-53b9-4441-ba9c-d69d4a4a6e38}"/>**, to your manifest file as follows. The transparent-eXGauge as a child of your form, it is supported on Windows 8, and later.

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<assembly manifestVersion="1.0" xmlns="urn:schemas-microsoft-com:asm.v1"
xmlns:asmv3="urn:schemas-microsoft-com:asm.v3">
  <compatibility xmlns="urn:schemas-microsoft-com:compatibility.v1">
    <application>
      <supportedOS Id="{4a2f28e3-53b9-4441-ba9c-d69d4a4a6e38}"/>
    </application>
  </compatibility>
</assembly>
```

The control installs the

- C:\Program Files\Exontrol\ExGauge\Sample\VB\Widget or C:\Program Files\Exontrol\ExGauge\Sample\VC\Widget sample that shows how exLayerUpdateScreenworks with LayerUpdate property.
- C:\Program Files\Exontrol\ExGauge\Sample\VC\Widget-Child sample that shows how exLayerUpdateParent works with LayerUpdate property

The following screen shot shows the control on a transparent form (**exLayerUpdateScreen**):

The following screen shot shows the transparent-control on form (**exLayerUpdateParent**):

www.exontrol.com

The message doesn't appear in the registered version.

property Gauge.PicturesName as String

Specifies the expression that indicates the name of the picture to be loaded on each layer.

Type	Description
String	A String value that defines the expression to specify the name of the picture to be loaded on each layer.

By default, the PicturesName property is empty. The [Picture.Name](#) / [Picture.Value](#) property is initialized by evaluating the control's PicturesName property, whose **value** keyword is replaced by the [Picture.Index](#) of the current layer.

The following properties can be used to load / import (manually or automatically) pictures to the layer's background:

- [PicturesPath](#) property, specifies the path to load pictures from.
- PicturesName property, specifies the expression that defines the name of the file from the PicturesPath folder to be loaded.
- [Picture.Name](#) / [Picture.Value](#) property of the Background.Picture object, defines the name of the file to be loaded (relative, absolute, encoded or Picture object)

The [PicturesPath](#) / PicturesName properties can be used to automatically loads files from a specified folder to be displayed on the layer's background. The [Picture.Name](#) / [Picture.Value](#) property of the Picture object loads a picture / graphics to be displayed on the layer's background.

For instance,

PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob",
defines default folder to load pictures from.

PicturesName = ""Layer` + str(value + 1) + `.png`", defines the name of the picture file to be loaded by the layer with the index / value. It defines the names as: Layer1.png for the layer with the index 0, Layer2.png for the layer with the index 1, Layer3.png for the layer with the index 2, and so on.

The PicturesName property supports the following keywords:

- **value** keyword, specifies the [Index](#) of the layer.

Also, this property supports all constants, operators and functions defined [here](#).

For instance, having the files Layer1.png, Layer2.png, Layer3.png, Layer4.png and Layer5.png in the C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob 2 folder:

We can load them using the [PicturesPath](#) / PicturesName property and we get something like:

or if we decompose them, layer by layer we get:

The following samples shows how you can load automatically the Layer1.png, Layer2.png, Layer3.png, Layer4.png and Layer5.png from the C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob 2 folder:

VBA (MS Access, Excell...)

```
With Gauge1
    .BeginUpdate
    .PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob
2"
    .PicturesName = ""Layer` + int(value + 1) + `.png""
    .Layers.Count = 5
    .EndUpdate
End With
```

VB6

```
With Gauge1
    .BeginUpdate
    .PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob
2"

```

property Gauge.PicturesPath as String

Specifies the path to load the pictures from.

Type	Description
String	A String expression that defines the folder to load pictures from

By default, the PicturesPath property is empty. The PicturesPath property specifies the path to load the pictures from. The [PicturesName](#) property specifies the expression that indicates the name of the picture to be loaded on each layer. The [Count](#) property specifies the number of layers in the control.

The following properties can be used to load / import (manually or automatically) pictures to the layer's background:

- PicturesPath property, specifies the path to load pictures from.
- [PicturesName](#) property, specifies the expression that defines the name of the file from the PicturesPath folder to be loaded. By default, the [Picture.Name](#) / [Picture.Value](#) property is initialized by evaluating the control's [PicturesName](#) property, whose **value** keyword is replaced by the [Picture.Index](#) of the current layer.
- [Picture.Name](#) / [Picture.Value](#) property of the Background.Picture object, defines the name of the file to be loaded (relative, absolute, encoded or Picture object)

The PicturesPath / [PicturesName](#) properties can be used to automatically loads files from a specified folder to be displayed on the layer's background.

For instance,

PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob",
defines default folder to load pictures from.

PicturesName = ""Layer` + str(value + 1) + `.png`", defines the name of the picture file to be loaded by the layer with the index / value. It defines the names as: Layer1.png for the layer with the index 0, Layer2.png for the layer with the index 1, Layer3.png for the layer with the index 2, and so on.

The [Picture.Name](#) / [Picture.Value](#) property of the Picture object loads a picture / graphics to be displayed on the layer's background.

For instance, having the files Layer1.png, Layer2.png, Layer3.png, Layer4.png and Layer5.png in the C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob 2 folder:

We can load them using the PicturesPath / [PicturesName](#) property and we get something like:

or if we decompose them, layer by layer we get:

The following samples shows how you can load automatically the Layer1.png, Layer2.png, Layer3.png, Layer4.png and Layer5.png from the C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob 2 folder:

VBA (MS Access, Excell...)

```
With Gauge1
    .BeginUpdate
    .PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob
2"
    .PicturesName = ""Layer` + int(value + 1) + `.png""
    .Layers.Count = 5
    .EndUpdate
End With
```

VB6

```
With Gauge1
    .BeginUpdate
    .PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob
2"
    .PicturesName = ""Layer` + int(value + 1) + `.png""
    .Layers.Count = 5
    .EndUpdate
End With
```

VB.NET

```
With Exgauge1
    .BeginUpdate()
    .PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob
2"
    .PicturesName = ""Layer` + int(value + 1) + `.png""
    .Layers.Count = 5
    .EndUpdate()
End With
```

VB.NET for /COM

```
With AxGauge1
    .BeginUpdate()
    .PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob
2"
```

```
.PicturesName = L"Layer` + int(value + 1) + `.png`"  
.Layers.Count = 5  
.EndUpdate()  
End With
```

C++

```
/*  
    Copy and paste the following directives to your header file as  
    it defines the namespace 'EXGAUGELib' for the library: 'ExGauge 1.0 Control

```

method Gauge.Refresh ()

Refreshes the control.

Type	Description
------	-------------

method Gauge.Replacelcon ([Icon as Variant], [Index as Variant])

Adds a new icon, replaces an icon or clears the control's image list.

Type	Description
Icon as Variant	A long expression that indicates the icon's handle.
Index as Variant	A long expression that indicates the index where icon is inserted.

Return	Description
Long	A long expression that indicates the index of the icon in the images collection

Use the Replacelcon property to add, remove or replace an icon in the control's images collection. Also, the Replacelcon property can clear the images collection. Use the [Images](#) method to attach a image list to the control. The [ImageSize](#) property defines the size (width/height) of the icons within the control's Images collection.

The following VB sample adds a new icon to control's images list:

```
i = ExGauge1.Replacelcon( LoadPicture("d:\icons\help.ico").Handle), i specifies the index where the icon is added
```

The following VB sample replaces an icon into control's images list::

```
i = ExGauge1.Replacelcon( LoadPicture("d:\icons\help.ico").Handle, 0), i is zero, so the first icon is replaced.
```

The following VB sample removes an icon from control's images list:

```
ExGauge1.Replacelcon 0, i, i specifies the index of icon removed.
```

The following VB clears the control's icons collection:

```
ExGauge1.Replacelcon 0, -1
```

property Gauge.ShowImageList as Boolean

Specifies whether the control's image list window is visible or hidden.

Type	Description
Boolean	A boolean expression that specifies whether the control's image list window is visible or hidden.

By default, the ShowImageList property is True. Use the ShowImageList property to hide the control's images list window. The control's images list window is visible only at design time. Use the [Images](#) method to associate an images list control to the tree control. Use the [ReplaceIcon](#) method to add, remove or clear icons in the control's images collection.

property Gauge.ShowLayers as String

Indicates the only layers to be shown on the control.

Type	Description
String	<p>A String expression that could be:</p> <ul style="list-style-type: none">• "all", specifies that all visible layers are shown. The Visible property indicates the visible layers.• "", no layer is shown in the control, no matter of the layer's Visible property.• "n1,n2,n3,..." specifies the list of layers to be shown, no matter of the layer's Visible property, where n1, n2, ... are numbers (indicating the index of the layer to be shown). For instance "0" specifies that just the layer with the index 0 is show, "0,1,4", indicates that just layers with the specified index are displayed.

By default the ShowLayers property is "all", which indicates that all visible layers in the control are shown. The ShowLayers property indicates the only layers to be shown on the control. For instance, you can use the ShowLayers property to show only a few layers within the control. The purpose can be debugging a specified layer only for instance. The [Visible](#) property shows or hides the layer.

The following properties can be used to access Layer objects in the control:

- [Item](#) property, gives the Layer object based on its index / key. The [Count](#) property specifies the number of layers within the control
- [VisibleItem](#) property, gives the visible layer based on its position. The VisibleCount property indicates the number of visible layers within the control. The [Visible](#) property shows or hides the layer. The [ShowLayers](#) property indicates the only layers to be shown on the control.

The following properties can be used to add layers within the control:

- [Count](#) property, adds layers to the control
- [Add](#) method, adds a new layer to the control.

The following properties can be used to remove layers within the control:

- [Count](#) property, removes layers from the control. For instance, Count property on 0, removes all layers from the control.
- [Clear](#) removes all layers from the control.

- [Remove](#) method, removes a layer from the control based on its index or key.

method Gauge.ShowToolTip (ToolTip as String, [Title as Variant], [Alignment as Variant], [X as Variant], [Y as Variant])

Shows the specified tooltip at given position.

Type	Description
ToolTip as String	<p>The ToolTip parameter can be any of the following:</p> <ul style="list-style-type: none">• NULL(BSTR) or "<null>"(string) to indicate that the tooltip for the object being hovered is not changed• A String expression that indicates the description of the tooltip, that supports built-in HTML format (adds, replaces or changes the object's tooltip)
Title as Variant	<p>The Title parameter can be any of the following:</p> <ul style="list-style-type: none">• missing (VT_EMPTY, VT_ERROR type) or "<null>" (string) the title for the object being hovered is not changed.• A String expression that indicates the title of the tooltip (no built-in HTML format) (adds, replaces or changes the object's title)
Alignment as Variant	<p>A long expression that indicates the alignment of the tooltip relative to the position of the cursor. If missing (VT_EMPTY, VT_ERROR) the alignment of the tooltip for the object being hovered is not changed.</p> <p>The Alignment parameter can be one of the following:</p> <ul style="list-style-type: none">• 0 - exTopLeft• 1 - exTopRight• 2 - exBottomLeft• 3 - exBottomRight• 0x10 - exCenter• 0x11 - exCenterLeft• 0x12 - exCenterRight• 0x13 - exCenterTop• 0x14 - exCenterBottom <p>By default, the tooltip is aligned relative to the top-left corner (0 - exTopLeft).</p>

Specifies the horizontal position to display the tooltip as one of the following:

- missing (VT_EMPTY, VT_ERROR type), indicates that the tooltip is shown on its default position / current cursor position (ignored)
- -1, indicates the current horizontal position of the cursor (current x-position)
- a numeric expression that indicates the horizontal screen position to show the tooltip (fixed screen x-position)
- a string expression that indicates the horizontal displacement relative to default position to show the tooltip (moved)

X as Variant

Specifies the vertical position to display the tooltip as one of the following:

- missing (VT_EMPTY, VT_ERROR type), indicates that the tooltip is shown on its default position / current cursor position (ignored)
- -1, indicates the current vertical position of the cursor (current y-position)
- a numeric expression that indicates the vertical screen position to show the tooltip (fixed screen y-position)
- a string expression that indicates the vertical displacement relative to default position to show the tooltip (displacement)

Y as Variant

Use the ShowToolTip method to display a custom tooltip at specified position or to update the object's tooltip, title or position. You can call the ShowToolTip method during the [MouseMove](#) event. Use the [ToolTipPopDelay](#) property specifies the period in ms of time the ToolTip remains visible if the mouse pointer is stationary within a control. The [ToolTipDelay](#) property specifies the time in ms that passes before the ToolTip appears. Use the [ToolTipWidth](#) property to specify the width of the tooltip window. Use the [ToolTipFont](#) property to change the tooltip's font. Use the [Background\(exToolTipAppearance\)](#) property indicates the visual appearance of the borders of the tooltips. Use the [Background\(exToolTipBackColor\)](#) property indicates the tooltip's background color. Use the [Background\(exToolTipForeColor\)](#) property indicates the tooltip's foreground color.

For instance:

- [ShowToolTip\(<null>, <null>, , +8, +8\)](#), shows the tooltip of the object moved relative

to its default position

- `ShowToolTip(<null>`,`new title`)`, adds, changes or replaces the title of the object's tooltip
- `ShowToolTip(`new content`)`, adds, changes or replaces the object's tooltip
- `ShowToolTip(`new content`,`new title`)`, shows the tooltip and title at current position
- `ShowToolTip(`new content`,`new title`,`+8`,`+8`)`, shows the tooltip and title moved relative to the current position
- `ShowToolTip(`new content`,``,`128,128`)`, displays the tooltip at a fixed position
- `ShowToolTip(``,``)`, hides the tooltip

The ToolTip parameter supports the built-in HTML format like follows:

- ` ... ` displays the text in **bold**
- `<i> ... </i>` displays the text in *italics*
- `<u> ... </u>` underlines the text
- `<s> ... </s>` Strike-through text
- `<a id;options> ... ` displays an [anchor](#) element that can be clicked. An anchor is a piece of text or some other object (for example an image) which marks the beginning and/or the end of a hypertext link. The `<a>` element is used to mark that piece of text (or inline image), and to give its hypertextual relationship to other documents. The control fires the *AnchorClick(AnchorID, Options)* event when the user clicks the anchor element. The *FormatAnchor* property customizes the visual effect for anchor elements.
- ` ... ` displays portions of text with a different font and/or different size. For instance, the "`bit`" draws the bit text using the Tahoma font, on size 12 pt. If the name of the font is missing, and instead size is present, the current font is used with a different size. For instance, "`bit`" displays the bit text using the current font, but with a different size.
- `<fgcolor rrggbb> ... </fgcolor>` or `<fgcolor=rrggb> ... </fgcolor>` displays text with a specified **foreground** color. The rr/gg/bb represents the red/green/blue values of the color in hexa values.
- `<bgcolor rrggbb> ... </bgcolor>` or `<bgcolor=rrggb> ... </bgcolor>` displays text with a specified **background** color. The rr/gg/bb represents the red/green/blue values of the color in hexa values.
- `<solidline rrggbb> ... </solidline>` or `<solidline=rrggb> ... </solidline>` draws a solid-line on the bottom side of the current text-line, of specified RGB color. The `<solidline> ... </solidline>` draws a black solid-line on the bottom side of the current text-line. The rr/gg/bb represents the red/green/blue values of the color in hexa values.
- `<dotline rrggbb> ... </dotline>` or `<dotline=rrggb> ... </dotline>` draws a dot-line on the bottom side of the current text-line, of specified RGB color. The `<dotline> ... </dotline>` draws a black dot-line on the bottom side of the current text-line. The rr/gg/bb represents the red/green/blue values of the color in hexa values.
- `<upline> ... </upline>` draws the line on the top side of the current text-line (requires `<solidline>` or `<dotline>`).

- **<r>** right aligns the text
- **<c>** centers the text
- **
** forces a line-break
- **number[:width]** inserts an icon inside the text. The number indicates the index of the icon being inserted. Use the Images method to assign a list of icons to your chart. The last 7 bits in the high significant byte of the number expression indicates the identifier of the skin being used to paint the object. Use the [Add](#) method to add new skins to the control. If you need to remove the skin appearance from a part of the control you need to reset the last 7 bits in the high significant byte of the color being applied to the part. The width is optional and indicates the width of the icon being inserted. Using the width option you can overwrite multiple icons getting a nice effect. By default, if the width field is missing, the width is 18 pixels.
- **key[:width]** inserts a custom size picture into the text being previously loaded using the HTMLPicture property. The Key parameter indicates the key of the picture being displayed. The Width parameter indicates a custom size, if you require to stretch the picture, else the original size of the picture is used.
- **&** glyph characters as **&**; (&), **<**; (<), **>**; (>), **&qout;** (") and **&#number;** (the character with specified code), For instance, the **€** displays the EUR character. The **&** ampersand is only recognized as markup when it is followed by a known letter or a #character and a digit. For instance if you want to display **bold** in HTML caption you can use **bold**;
- **<off offset> ... </off>** defines the vertical offset to display the text/element. The offset parameter defines the offset to display the element. This tag is inheritable, so the offset is keep while the associated **</off>** tag is found. You can use the **<off offset>** HTML tag in combination with the **** to define a smaller or a larger font to be displayed. For instance: "Text with **<off 6>subscript**" displays the text such as: Text with subscript The "Text with **<off -6>superscript**" displays the text such as: Text with superscript
- **<gra rrggbb;mode;blend> ... </gra>** defines a gradient text. The text color or **<fgcolor>** defines the starting gradient color, while the rr/gg/bb represents the red/green/blue values of the ending color, 808080 if missing as gray. The mode is a value between 0 and 4, 1 if missing, and blend could be 0 or 1, 0 if missing. The **** HTML tag can be used to define the height of the font. Any of the rrggbb, mode or blend field may not be specified. The **<gra>** with no fields, shows a vertical gradient color from the current text color to gray (808080). For instance the "**<gra FFFFFFFF;1;1>gradient-center</gra>**" generates the following picture:

gradient-center

- **<out rrggbb;width> ... </out>** shows the text with outlined characters, where rr/gg/bb represents the red/green/blue values of the outline color, 808080 if missing as gray, width indicates the size of the outline, 1 if missing. The text color or **<fgcolor>** defines the color to show the inside text. The **** HTML tag can be used to define the

height of the font. For instance the "<out 000000>

<fgcolor=FFFFFF>outlined</fgcolor></out>" generates the following picture:

outlined

- <sha rrggbb;width;offset> ... </sha> define a text with a shadow, where rr/gg/bb represents the red/green/blue values of the shadow color, 808080 if missing as gray, width indicates the size of shadow, 4 if missing, and offset indicates the offset from the origin to display the text's shadow, 2 if missing. The text color or <fgcolor> defines the color to show the inside text. The HTML tag can be used to define the height of the font. For instance the "<sha>shadow</sha>" generates the following picture:

shadow

or "<sha 404040;5;0><fgcolor=FFFFFF>outline anti-aliasing</fgcolor></sha>" gets:

outline anti-aliasing

property Gauge.Template as String

Specifies the control's template.

Type	Description
String	A string expression that defines the control's template

The control's template uses the X-Script language to initialize the control's content. Use the Template property page of the control to update the control's Template property. Use the Template property to execute code by passing instructions as a string (template string). Use the [ToTemplate](#) property to generate the control's content to template format. Use the [ExecuteTemplate](#) property to get the result of executing a template script.

The Exontrol's [eXHelper](#) tool helps you to find easy and quickly the answers and the source code for your questions regarding the usage of our UI components.

Most of our UI components provide a Template page that's accessible in design mode. No matter what programming language you are using, you can have a quick view of the component's features using the WYSWYG Template editor.

- Place the control to your form or dialog.
- Locate the Properties item, in the control's context menu, in design mode. If your environment doesn't provide a Properties item in the control's context menu, please try to locate in the Properties browser.
- Click it, and locate the Template page.
- Click the Help button. In the left side, you will see the component, in the right side, you will see a x-script code that calls methods and properties of the control.

The control's Template page helps user to initialize the control's look and feel in design mode, using the x-script language that's easy and powerful. The Template page displays the control on the left side of the page. On the right side of the Template page, a simple editor is displayed where user writes the initialization code. The control's look and feel is automatically updated as soon as the user types new instructions. The Template script is saved to the container persistence (when Apply button is pressed), and it is executed when the control is initialized at runtime. Any component that provides a WYSWYG Template page, provides a Template property. The Template property executes code from a string (template string).

The Template or x-script is composed by lines of instructions. Instructions are separated by "\n\r" (newline characters) or ";" character. The ; character may be available only for newer versions of the components.

An x-script instruction/line can be one of the following:

- **Dim** list of variables *Declares the variables. Multiple variables are separated by commas. (Sample: Dim h, h1, h2)*
- **variable = property(list of arguments)** *Assigns the result of the property to a variable. The "variable" is the name of a declared variable. The "property" is the property name of the object in the context. The "list or arguments" may include variables or values separated by commas. (Sample: h = InsertItem(0,"New Child"))*
- **property(list of arguments) = value** *Changes the property. The value can be a variable, a string, a number, a boolean value or a RGB value.*
- **method(list of arguments)** *Invokes the method. The "list or arguments" may include variables or values separated by commas.*
- **{** *Beginning the object's context. The properties or methods called between { and } are related to the last object returned by the property prior to { declaration.*
- **}** *Ending the object's context*
- **object.property(list of arguments).property(list of arguments)....** *The .(dot) character splits the object from its property. For instance, the Columns.Add("Column1").HeaderBackColor = RGB(255,0,0), adds a new column and changes the column's header back color.*

The x-script may uses constant expressions as follow:

- *boolean* expression with possible values as *True* or *False*
- *numeric* expression may starts with 0x which indicates a hexa decimal representation, else it should starts with digit, or +/- followed by a digit, and . is the decimal separator. *Sample: 13 indicates the integer 13, or 12.45 indicates the double expression 12,45*
- *date* expression is delimited by # character in the format #mm/dd/yyyy hh:mm:ss#. *Sample: #31/12/1971# indicates the December 31, 1971*
- *string* expression is delimited by " or ` characters. If using the ` character, please make sure that it is different than ' which allows adding comments inline. *Sample: "text" indicates the string text.*

Also , the template or x-script code may support general functions as follows:

- **Me** *property indicates the original object.*
- **RGB(R,G,B)** *property retrieves an RGB value, where the R, G, B are byte values that indicates the R G B values for the color being specified. For instance, the following code changes the control's background color to red: BackColor = RGB(255,0,0)*
- **LoadPicture(file)** *property loads a picture from a file or from BASE64 encoded strings, and returns a Picture object required by the picture properties.*
- **CreateObject(progID)** *property creates and retrieves a single uninitialized object of the class associated with a specified program identifier.*

For instance, the following script:

```
PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob"
```

```
PicturesName = "`Layer` + str(value + 1) + `.png`"
```

```
Layers.Count = 10
```

generates:

property Gauge.TemplateDef as Variant

Defines inside variables for the next Template/ExecuteTemplate call.

Type	Description
Variant	A string expression that indicates the Dim declaration, or any Object expression to be assigned to previously declared variables.

The TemplateDef property has been added to allow programming languages such as dBASE Plus to set control's properties with multiple parameters. It is known that programming languages such as **dBASE Plus** or **XBasic from AlphaFive**, does not support setting a property with multiple parameters. In other words, these programming languages does not support something like *Property(Parameters) = Value*, so our controls provide an alternative using the TemplateDef method. The first call of the TemplateDef should be a declaration such as "Dim a,b" which means the next 2 calls of the TemplateDef defines the variables a and b. The next call should be [Template](#) or [ExecuteTemplate](#) property which can use the variable a and b being defined previously.

So, calling the TemplateDef property should be as follows:

```
with (Control)
    TemplateDef = [Dim var_Column]
    TemplateDef = var_Column
    Template = [var_Column.Def(4) = 255]
endwith
```

This sample allocates a variable var_Column, assigns the value to the variable (the second call of the TemplateDef), and the Template call uses the var_Column variable (as an object), to call its Def property with the parameter 4.

Let's say we need to define the background color for a specified column, so we need to call the Def(exCellBackColor) property of the column, to define the color for all cells in the column.

The following **VB6** sample shows setting the Def property such as:

```
With Control
    .Columns.Add("Column 1").Def(exCellBackColor) = 255
    .Columns.Add "Column 2"
    .Items.AddItem 0
    .Items.AddItem 1
```

```
.Items.AddItem 2  
End With
```

In **dBASE Plus**, calling the Def(4) has no effect, instead using the TemplateDef helps you to use properly the Def property as follows:

```
local Control,var_Column  
  
Control = form.ActiveX1.nativeObject  
// Control.Columns.Add("Column 1").Def(4) = 255  
var_Column = Control.Columns.Add("Column 1")  
with (Control)  
    TemplateDef = [Dim var_Column]  
    TemplateDef = var_Column  
    Template = [var_Column.Def(4) = 255]  
endwith  
Control.Columns.Add("Column 2")  
Control.Items.AddItem(0)  
Control.Items.AddItem(1)  
Control.Items.AddItem(2)
```

The equivalent sample for **XBasic in A5**, is as follows:

```
Dim Control as P  
Dim var_Column as P  
  
Control = topparent:CONTROL_ACTIVEX1.activex  
' Control.Columns.Add("Column 1").Def(4) = 255  
var_Column = Control.Columns.Add("Column 1")  
Control.TemplateDef = "Dim var_Column"  
Control.TemplateDef = var_Column  
Control.Template = "var_Column.Def(4) = 255"  
  
Control.Columns.Add("Column 2")  
Control.Items.AddItem(0)  
Control.Items.AddItem(1)  
Control.Items.AddItem(2)
```

The samples just call the `Column.Def(4) = Value`, using the `TemplateDef`. The first call of `TemplateDef` property is `"Dim var_Column"`, which indicates that the next call of the `TemplateDef` will defines the value of the variable `var_Column`, in other words, it defines the object `var_Column`. The last call of the `Template` property uses the `var_Column` member to use the x-script and so to set the `Def` property so a new color is being assigned to the column.

The `TemplateDef`, [Template](#) and [ExecuteTemplate](#) support x-script language (`Template` script of the `Exontrols`), like explained bellow:

The `Template` or x-script is composed by lines of instructions. Instructions are separated by `"\n\r"` (newline characters) or `";"` character. The `;` character may be available only for newer versions of the components.

An x-script instruction/line can be one of the following:

- **Dim** list of variables *Declares the variables. Multiple variables are separated by commas.* (Sample: `Dim h, h1, h2`)
- `variable = property(list of arguments)` *Assigns the result of the property to a variable. The "variable" is the name of a declared variable. The "property" is the property name of the object in the context. The "list or arguments" may include variables or values separated by commas.* (Sample: `h = InsertItem(0,"New Child")`)
- `property(list of arguments) = value` *Changes the property. The value can be a variable, a string, a number, a boolean value or a RGB value.*
- `method(list of arguments)` *Invokes the method. The "list or arguments" may include variables or values separated by commas.*
- `{` *Beginning the object's context. The properties or methods called between `{` and `}` are related to the last object returned by the property prior to `{` declaration.*
- `}` *Ending the object's context*
- `object.property(list of arguments).property(list of arguments)....` *The `.` (dot) character splits the object from its property. For instance, the `Columns.Add("Column1").HeaderBackColor = RGB(255,0,0)`, adds a new column and changes the column's header back color.*

The x-script may uses constant expressions as follow:

- *boolean* expression with possible values as *True* or *False*
- *numeric* expression may starts with `0x` which indicates a hexa decimal representation, else it should starts with digit, or `+/-` followed by a digit, and `.` is the decimal separator. Sample: `13` indicates the integer `13`, or `12.45` indicates the double expression `12,45`
- *date* expression is delimited by `#` character in the format `#mm/dd/yyyy hh:mm:ss#`. Sample: `#31/12/1971#` indicates the December 31, 1971
- *string* expression is delimited by `"` or ``` characters. If using the ``` character, please

make sure that it is different than ' which allows adding comments inline. *Sample: "text" indicates the string text.*

Also , the template or x-script code may support general functions as follows:

- **Me** *property indicates the original object.*
- **RGB(R,G,B)** *property retrieves an RGB value, where the R, G, B are byte values that indicates the R G B values for the color being specified. For instance, the following code changes the control's background color to red: BackColor = RGB(255,0,0)*
- **LoadPicture(file)** *property loads a picture from a file or from BASE64 encoded strings, and returns a Picture object required by the picture properties.*
- **CreateObject(progID)** *property creates and retrieves a single uninitialized object of the class associated with a specified program identifier.*

method gauge.TemplatePut (NewVal as Variant)

Defines inside variables for the next Template/ExecuteTemplate call.

Type	Description
NewVal as Variant	A string expression that indicates the Dim declaration, or any Object expression to be assigned to previously declared variables.

The TemplatePut method / [TemplateDef](#) property has been added to allow programming languages such as dBASE Plus to set control's properties with multiple parameters. It is known that programming languages such as **dBASE Plus** or **XBasic from AlphaFive**, does not support setting a property with multiple parameters. In other words, these programming languages does not support something like *Property(Parameters) = Value*, so our controls provide an alternative using the TemplateDef / TemplatePut method. The first call of the TemplateDef should be a declaration such as "Dim a,b" which means the next 2 calls of the TemplateDef defines the variables a and b. The next call should be [Template](#) or [ExecuteTemplate](#) property which can use the variable a and b being defined previously.

The [TemplateDef](#), TemplatePut, [Template](#) and [ExecuteTemplate](#) support x-script language (Template script of the Exontrols), like explained bellow:

The Template or x-script is composed by lines of instructions. Instructions are separated by "\n\r" (newline characters) or ";" character. The ; character may be available only for newer versions of the components.

An x-script instruction/line can be one of the following:

- **Dim** list of variables *Declares the variables. Multiple variables are separated by commas.* (Sample: Dim h, h1, h2)
- variable = property(list of arguments) *Assigns the result of the property to a variable. The "variable" is the name of a declared variable. The "property" is the property name of the object in the context. The "list or arguments" may include variables or values separated by commas.* (Sample: h = InsertItem(0,"New Child"))
- property(list of arguments) = value *Changes the property. The value can be a variable, a string, a number, a boolean value or a RGB value.*
- method(list of arguments) *Invokes the method. The "list or arguments" may include variables or values separated by commas.*
- { *Beginning the object's context. The properties or methods called between { and } are related to the last object returned by the property prior to { declaration.*
- } *Ending the object's context*
- object. property(list of arguments).property(list of arguments).... *The .(dot) character splits the object from its property. For instance, the*

Columns.Add("Column1").HeaderBackColor = RGB(255,0,0), adds a new column and changes the column's header back color.

The x-script may use constant expressions as follows:

- *boolean* expression with possible values as *True* or *False*
- *numeric* expression may start with 0x which indicates a hexa decimal representation, else it should start with digit, or +/- followed by a digit, and . is the decimal separator. *Sample: 13 indicates the integer 13, or 12.45 indicates the double expression 12,45*
- *date* expression is delimited by # character in the format #mm/dd/yyyy hh:mm:ss#. *Sample: #31/12/1971# indicates the December 31, 1971*
- *string* expression is delimited by " or ` characters. If using the ` character, please make sure that it is different than ' which allows adding comments inline. *Sample: "text" indicates the string text.*

Also, the template or x-script code may support general functions as follows:

- **Me** property indicates the original object.
- **RGB(R,G,B)** property retrieves an RGB value, where the R, G, B are byte values that indicate the R G B values for the color being specified. For instance, the following code changes the control's background color to red: *BackColor = RGB(255,0,0)*
- **LoadPicture(file)** property loads a picture from a file or from BASE64 encoded strings, and returns a Picture object required by the picture properties.
- **CreateObject(progID)** property creates and retrieves a single uninitialized object of the class associated with a specified program identifier.

property Gauge.TimerInterval as Long

Returns or sets the number of milliseconds between calls of control's Timer event.

Type	Description
Long	A Long expression that specifies the number of milliseconds between calls of control's Timer event.

By default, the TimerInterval property is 0, which indicates that no [Timer](#) event occurs. The TimerInterval property returns or sets the number of milliseconds between calls of control's [Timer](#) event. You can use the [Timer](#) event to perform different actions on any layer when a specified time elapsed. For instance, you can rotate the layer every second, or any dial of a clock, and so on. The [FormatABC](#) method formats the A,B,C values based on the giving expression and returns the result. For instance, the FormatABC("date(`now`)") gets the current time.

You can use any of the following properties to update the layer:

- [Value](#), specifies the layer's value.
- [OffsetX](#), specifies a value that indicates x-offset of the layer.
- [OffsetY](#), indicates a value that indicates y-offset of the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [Clip](#), to clip any layer

The [Change](#) event occurs when the layer's value is changed.

The following sample shows how you can display a clock:

VBA (MS Access, Excell...)

```
' Change event - Occurs when the layer's value is changed.
Private Sub Gauge1_Change(ByVal Layer As Long)
    With Gauge1
```

```

.Layers.Item("sec").Value = Gauge1.Value
.Layers.Item("min").Value = Gauge1.Value
.Layers.Item("hour").Value = Gauge1.Value
End With
End Sub

' Timer event - Occurs when the interval elapses.
Private Sub Gauge1_Timer(ByVal TickCount As Long)
    With Gauge1
        .Value = .FormatABC("value + 1/24/60/60",.Value)
    End With
End Sub

With Gauge1
    .PicturesPath = "C:\Program
Files\Exontrol\ExGauge\Sample\Design\Circular\Clock"
    .DefaultLayer(185) = 2
    .Layers.Count = 4
    With .Layers.Item(0)
        .Background.Picture.Name = "vista_clock.png"
    End With
    With .Layers.Item(1)
        .Position = 3
        .Key = "sec"
        .OnDrag = 2
        .Selectable = False
        .Background.Picture.Name = "second-hand.png"
        .ValueToRotateAngle = "((2:=(((1:=( ( (0:=(value < 0 ? floor(value) + 1 - value :
value - floor(value))) < 0.5 ? =:0 : (0:= (=:0 - 0.5)) ) * 24 )) - " & _
"floor(=:1)) * 60 )) - floor(=:2) ) * 360"
        .RotateAngleToValue = "value / 360 / 24 / 60"
    End With
    With .Layers.Item(2)
        .Position = 2
        .Key = "min"
        .OnDrag = 2
        .Selectable = False

```

```

        .Background.Picture.Name = "Minute.png"
        .ValueToRotateAngle = "((1:=( ( (0:=(value < 0 ? floor(value) + 1 - value : value - floor(value))) < 0.5 ? =:0 : (0:= (=:0 - 0.5)) ) * 24 )) - floor(" & _
"=:1)) * 360"
        .RotateAngleToValue = "value / 360 / 24 / 60"
End With
With .Layers.Item(3)

property Gauge.ToolTipDelay as Long

Specifies the time in ms that passes before the ToolTip appears.

Type	Description
Long	A Long expression that specifies the time in ms that passes before the ToolTip appears.

By default, the ToolTipDelay property is 500, which indicates that the tooltip is shown after 0.5 seconds. Use the [ToolTipPopDelay](#) property specifies the period in ms of time the ToolTip remains visible if the mouse pointer is stationary within a control. Use the [ToolTipFont](#) property to change the tooltip's font. Use the [ShowToolTip](#) method to display a custom tooltip. The [ToolTip](#) / [ToolTipTitle](#) property indicates the layer's tooltip. The [LayerFromPoint](#) property returns the index of the layer from the cursor. Use the [ToolTipWidth](#) property to specify the width of the tooltip window Use the [Background\(exToolTipAppearance\)](#) property indicates the visual appearance of the borders of the tooltips. Use the [Background\(exToolTipBackColor\)](#) property indicates the tooltip's background color. Use the [Background\(exToolTipForeColor\)](#) property indicates the tooltip's foreground color.

property Gauge.ToolTipFont as IFontDisp

Retrieves or sets the tooltip's font.

Type	Description
IFontDisp	A Font object to be used by the control's tooltip.

Use the ToolTipFont property to change the tooltip's font. Use the [ShowToolTip](#) method to display a custom tooltip. The [ToolTip](#) / [ToolTipTitle](#) property indicates the layer's tooltip. The [LayerFromPoint](#) property returns the index of the layer from the cursor. Use the [ToolTipWidth](#) property to specify the width of the tooltip window Use the [ToolTipPopDelay](#) property specifies the period in ms of time the ToolTip remains visible if the mouse pointer is stationary within a control. Use the [Background\(exToolTipAppearance\)](#) property indicates the visual appearance of the borders of the tooltips. Use the [Background\(exToolTipBackColor\)](#) property indicates the tooltip's background color. Use the [Background\(exToolTipForeColor\)](#) property indicates the tooltip's foreground color.

property Gauge.ToolTipPopDelay as Long

Specifies the period in ms of time the ToolTip remains visible if the mouse pointer is stationary within a control.

Type	Description
Long	A Long expression that specifies the period in ms of time the ToolTip remains visible if the mouse pointer is stationary within a control.

By default, the ToolTipPopDelay property is 5000, which indicates that the tooltip remains visible for 5 seconds, while the cursor is not moved. Use the ToolTipPopDelay property specifies the period in ms of time the ToolTip remains visible if the mouse pointer is stationary within a control. Use the [ToolTipFont](#) property to change the tooltip's font. Use the [ShowToolTip](#) method to display a custom tooltip. The [ToolTip](#) / [ToolTipTitle](#) property indicates the layer's tooltip. The [LayerFromPoint](#) property returns the index of the layer from the cursor. Use the [ToolTipWidth](#) property to specify the width of the tooltip window Use the [Background\(exToolTipAppearance\)](#) property indicates the visual appearance of the borders of the tooltips. Use the [Background\(exToolTipBackColor\)](#) property indicates the tooltip's background color. Use the [Background\(exToolTipForeColor\)](#) property indicates the tooltip's foreground color.

property Gauge.ToolTipWidth as Long

Specifies a value that indicates the width of the tooltip window, in pixels.

Type	Description
Long	A Long expression that that indicates the width of the tooltip window, in pixels.

By default, the ToolTipWidth property is 196 pixels. Use the ToolTipWidth property to specify the width of the tooltip window. Use the [ShowToolTip](#) method to display a custom tooltip. The [ToolTip](#) / [ToolTipTitle](#) property indicates the layer's tooltip. The [ToolTipDelay](#) property specifies the time in ms that passes before the ToolTip appears. The [LayerFromPoint](#) property returns the index of the layer from the cursor. Use the [ToolTipPopDelay](#) property specifies the period in ms of time the ToolTip remains visible if the mouse pointer is stationary within a control. Use the [ToolTipFont](#) property to change the tooltip's font. Use the [Background\(exToolTipAppearance\)](#) property indicates the visual appearance of the borders of the tooltips. Use the [Background\(exToolTipBackColor\)](#) property indicates the tooltip's background color. Use the [Background\(exToolTipForeColor\)](#) property indicates the tooltip's foreground color.

property Gauge.ToTemplate ([DefaultTemplate as Variant]) as String

Generates the control's template.

Type	Description
DefaultTemplate as Variant	A String expression that indicates the default format used to define the control's template at runtime, or a string expression that indicates the path to the file being used to define the default template (like c:\temp\templ.bin). If it is missing (by default), the control's uses the default implementation (listed bellow) to define the control's template, at runtime. Each line in the DefaultTemplate parameter, defines a property or an instruction to generate the template.
String	A String expression that indicates the control's template.

Use the ToTemplate property to save the control's content to a template string. The ToTemplate property saves the control's properties based on the default template. Use the ToTemplate property to copy the control's content to another instance. The ToTemplate property can save pictures, icons, binary arrays, objects, collections, and so on based on the DefaultTemplate parameter.

The DefaultTemplate parameter indicates the format of the template being used to generate the control's template at runtime. If the DefaultTemplate parameter is missing, the control's uses its default template listed bellow. The DefaultTemplate parameter defines the list of properties and instructions that generates the control's template. Remove the properties and objects, in the default template, that you don't need in the generated template script. Use the [Template](#) property to apply the template to the control. Use the Template property to execute code by passing instructions as a string (template string). The Template script is composed by lines of instructions. Instructions are separated by "\n\r" (newline) characters. The Template format contains a list of instructions that loads data and change properties for the objects in the control. Use the [AllowCopyTemplate](#) property to copy the control's content to the clipboard, in template format, using the the Shift + Ctrl + Alt + Insert sequence.

property Gauge.TransparentColorFrom as Color

Specifies the transparent color for all pictures in all layers, to define transparency part (from).

Type	Description
Color	A Color expression that defines the transparent color to be applied on all pictures on any layer.

By default, the TransparentColorFrom property is RGB(255, 255, 255) and TransparentColorTo property is -1, which indicates that pixels of white colors are transparent. The TransparentColorFrom property defines the transparent color for all pictures on any layer, that has the [TransparentColorFrom](#) property on -1 (by default). The [TransparentColorTo](#) defines the second transparent color, to define transparent pixels between a range of colors. The [Opaque](#) property indicates if the picture is shown as opaque or transparent.

The TransparentColorFrom / TransparentColorTo properties have effect it:

- [Opaque](#) property is False (by default)
- picture's attribute does **not** include the PICTURE_TRANSPARENT flag (for instance a PNG picture with transparency, includes the PICTURE_TRANSPARENT flag)
- TransparentColorFrom / TransparentColorTo properties points to valid colors (different than -1 value). For instance, if one property is defined and the other is -1, the first one defines the transparent pixels, while if both are specified and points to value different than -1, any pixel between them is considered as transparent.

If The TransparentColorFrom / TransparentColorTo properties have effect, any picture where these apply defines the pixels as:

- any pixel with a color between TransparentColorFrom and TransparentColorTo is defined as transparent
- any other pixel that's not transparent is opaque.

If using the **PNG** format, the control handles automatically its transparency / alpha blending (if saved with transparency), unless the [Opaque](#) property is True, so in this case, any TransparentColorFrom or TransparentColorTo property has no effect.

For any other picture type, you can use any of the following to define the transparent region of the picture:

- TransparentColorFrom, specifies the transparent color to define transparency part of the current picture (to).
- TransparentColorTo, specifies the transparent color to define transparency part of the

current picture (to).

The control supports almost all type of pictures like

- **PNG** (Portable Network Graphics) is a raster graphics file format that supports lossless data compression. PNG was created as an improved, non-patented replacement for Graphics Interchange Format (GIF), and is the most used lossless image compression format on the Internet
- **BMP** file format, also known as bitmap image file or device independent bitmap (DIB) file format or simply a bitmap, is a raster graphics image file format used to store bitmap digital images, independently of the display device (such as a graphics adapter)
- **JPEG** file format (seen most often with the .jpg extension) is a commonly used method of lossy compression for digital images, particularly for those images produced by digital photography.
- **GIF** (Graphics Interchange Format) is a bitmap image format that was introduced by CompuServe in 1987 and has since come into widespread usage on the World Wide Web due to its wide support and portability.
- **TIFF** (Tagged Image File Format) is a computer file format for storing raster graphics images, popular among graphic artists, the publishing industry, and both amateur and professional photographers in general.

property Gauge.TransparentColorTo as Color

Specifies the transparent color for all pictures in all layers, to define transparency part (to).

Type	Description
Color	A Color expression that defines the second transparent color to be applied on all pictures on any layer.

By default, the [TransparentColorFrom](#) property is RGB(255, 255, 255) and TransparentColorTo property is -1, which indicates that pixels of white colors are transparent. The TransparentColorFrom property defines the transparent color for all pictures on any layer, that has the [TransparentColorFrom](#) property on -1 (by default). The TransparentColorTo defines the second transparent color, to define transparent pixels between a range of colors. The [Opaque](#) property indicates if the picture is shown as opaque or transparent.

The TransparentColorFrom / TransparentColorTo properties have effect it:

- [Opaque](#) property is False (by default)
- picture's attribute does **not** include the PICTURE_TRANSPARENT flag (for instance a PNG picture with transparency, includes the PICTURE_TRANSPARENT flag)
- TransparentColorFrom / TransparentColorTo properties points to valid colors (different than -1 value). For instance, if one property is defined and the other is -1, the first one defines the transparent pixels, while if both are specified and points to value different than -1, any pixel between them is considered as transparent.

If The TransparentColorFrom / TransparentColorTo properties have effect, any picture where these apply defines the pixels as:

- any pixel with a color between TransparentColorFrom and TransparentColorTo is defined as transparent
- any other pixel that's not transparent is opaque.

If using the **PNG** format, the control handles automatically its transparency / alpha blending (if saved with transparency), unless the [Opaque](#) property is True, so in this case, any TransparentColorFrom or TransparentColorTo property has no effect.

For any other picture type, you can use any of the following to define the transparent region of the picture:

- TransparentColorFrom, specifies the transparent color to define transparency part of the current picture (to).
- TransparentColorTo, specifies the transparent color to define transparency part of the current picture (to).

The control supports almost all type of pictures like

- **PNG** (Portable Network Graphics) is a raster graphics file format that supports lossless data compression. PNG was created as an improved, non-patented replacement for Graphics Interchange Format (GIF), and is the most used lossless image compression format on the Internet
- **BMP** file format, also known as bitmap image file or device independent bitmap (DIB) file format or simply a bitmap, is a raster graphics image file format used to store bitmap digital images, independently of the display device (such as a graphics adapter)
- **JPEG** file format (seen most often with the .jpg extension) is a commonly used method of lossy compression for digital images, particularly for those images produced by digital photography.
- **GIF** (Graphics Interchange Format) is a bitmap image format that was introduced by CompuServe in 1987 and has since come into widespread usage on the World Wide Web due to its wide support and portability.
- **TIFF** (Tagged Image File Format) is a computer file format for storing raster graphics images, popular among graphic artists, the publishing industry, and both amateur and professional photographers in general.

property Gauge.Value as Variant

Specifies the control's value.

Type	Description
Variant	A VARIANT expression that specifies the value associated with the control.

By default, the Value property is empty. The layer's [Value](#) could indicate its offset or its rotation angle, based on the [OnDrag](#) property. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (draggable). Use the [Value](#) property of the Clip object to associate a value with the layer's clipping region. Each layer can associate a value with it, while the control's Value property can be associated through the [LayerOfValue](#) property with the value of one of the layers within the control.

For instance:

- the control displays a clock, the value could be the current-time
- the control shows a switch, so the value could indicate the state of the switch
- the control shows a thermometer, so the value could be the current temperature
- the control displays a gauge, so the value could be the value on the gauge pointed by the needle

The [Change](#) event occurs when the layer's Value property is changed. During the Change event, you can change values of other layers as well. For instance, if the second-hand of the clock is rotated, you can rotate the hour and the minute-hands of the clock as well. The [DragStart](#) / [Drag](#) / [DragEnd](#) events notify your application when a layer is dragged. *You can call `DragInfo.Debug = -1` during the [DragStart](#) event to display debugging information like current movement, rotation angle when drag operation is performed.*

The Value property indicates the **value** keyword in the following properties:

- [ValueToOffsetX](#), Specifies the expression to convert the value to x-offset. The layer's [OffsetX](#) property is the result of evaluating the [ValueToOffsetX](#) expression, while the [OnDrag](#) property is **exDoMove**. The [OffsetToValue](#) converts the current offset to a value.
- [ValueToOffsetY](#), Specifies the expression to convert the value to y-offset. The layer's [OffsetY](#) property is the result of evaluating the [ValueToOffsetY](#) expression, while the [OnDrag](#) property is **exDoMove**. The [OffsetToValue](#) converts the current offset to a value.
- [ValueToRotateAngle](#), Specifies the expression to convert the value to rotating angle. The layer's [RotateAngle](#) property is the result of evaluating the [ValueToRotateAngle](#) expression, while the [OnDrag](#) property is **exDoRotate** or **exDoRotamove**. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The Value property works in association with the layer's [OnDrag](#) property like follows:

- If the [OnDrag](#) property is **exDoMove**, evaluating the [ValueToOffsetX](#) property indicates the layer's [OffsetX](#) property.
- If the [OnDrag](#) property is **exDoMove**, evaluating the [ValueToOffsetY](#) property indicates the layer's [OffsetY](#) property.
- If the [OnDrag](#) property is **exDoRotate** or **exDoRotamove**, evaluating the [ValueToRotateAngle](#) property indicates the layer's [RotateAngle](#) property.

For instance, having the gauge from the C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Guage folder, which includes the background and the needle pictures:

we need to define the value of the needle to be between 0 and 100, so if we call Value property on 85 we should get something like:

In conclusion, what we need to do is:

- defines the "needle" layer as rotate able, using the [OnDrag](#) property
- converts the value of 0-100, to a rotation angle, using the [ValueToRotateAngle](#) property
- converts the rotation angle from 0-360 to the value, using the [RotateAngleToValue](#) property
- limits the rotation angle, using the [RotateAngleValid](#) property

The following samples shows how you can do that:

VBA (MS Access, Excell...)

```
With Gauge1
    .BeginUpdate
    .DefaultLayer(185) = 2
    .BackColor = RGB(217,217,217)
    .PicturesPath = "C:\Program
Files\Exontrol\ExGauge\Sample\Design\Circular\Guage"
    With .Layers.Add("background")
        .Background.Picture.Name = "Guage_Background.png"
        .RotateCenterY = "Iheight/2 + 78"
    End With
    With .Layers.Add("needle")
        .Background.Picture.Name = "Guage_Needle.png"
```

```

.OnDrag = 2
.RotateAngleValid = "value < 90 ? value : (value < 180 ? 90 : ( value < 270 ? 270 :
value ))"
.RotateAngleToValue = "value >= 270 ? (value - 270)/90*50 : (value/90)*50 + 50"
.ValueToRotateAngle = "value < 50 ? (270 + value/50*90) : (value - 50)/50 * 90"
End With
.Value = 85
.EndUpdate
End With

```

VB6

```

With Gauge1
.BeginUpdate
.DefaultLayer(exDefLayerRotateType) = 2
.BackColor = RGB(217,217,217)
.PicturesPath = "C:\Program
Files\Exontrol\ExGauge\Sample\Design\Circular\Guage"
With .Layers.Add("background")
.Background.Picture.Name = "Guage_Background.png"
.RotateCenterY = "lheight/2 + 78"
End With
With .Layers.Add("needle")
.Background.Picture.Name = "Guage_Needle.png"
.OnDrag = exDoRotate
.RotateAngleValid = "value < 90 ? value : (value < 180 ? 90 : ( value < 270 ? 270 :
value ))"
.RotateAngleToValue = "value >= 270 ? (value - 270)/90*50 : (value/90)*50 + 50"
.ValueToRotateAngle = "value < 50 ? (270 + value/50*90) : (value - 50)/50 * 90"
End With
.Value = 85
.EndUpdate
End With

```

VB.NET

```

With Exgauge1
.BeginUpdate()

```

```

.set_DefaultLayer(exontrol.EXGAUGELib.DefaultLayerPropertyEnum.exDefLayerRotateTy

    .BackColor = Color.FromArgb(217,217,217)
    .PicturesPath = "C:\Program

RETURN

property Gauge.Version as String

Retrieves the control's version.

Type	Description
String	A string expression that indicates the control's version.

The version property specifies the control's version.

property Gauge.VisualAppearance as Appearance

Retrieves the control's appearance.

Type	Description
Appearance	An Appearance object that holds a collection of skins.

Use the [Add](#) method to add or replace skins to the control. The skin method, in it's simplest form, uses a single graphic file (*.ebn) assigned to a part of the control. By using a collection of objects laid over the graphic, it is possible to define which sections of the graphic will be used as borders, corners and other possible elements, fixing them to their proper position regardless of the size of the part.

Layer object

The Layer object holds a collection of pictures and HTML captions to be displayed on a viewable layer. Any layer can be visible, selectable or draggable. Any layer can be moved, rotated or clipped. The [Item](#) property of the Layers collection access a Layer object of the control. The [Background](#) / [Foreground](#) defines the layer's background and foreground.

The following screen shot shows combination of pictures and HTML captions, on different controls:

The Layer object supports the following properties and methods:

Name	Description
Background	Gets access to the layer's background object.
Brightness	Specifies the percent of brightness to apply to the layer.
Clip	Gets access to the layer's clip object.
Contrast	Specifies the percent of contrast to apply to the layer.
DefaultOffsetX	Gets or sets a value that indicates the default x-offset of the layer.
DefaultOffsetY	Gets or sets a value that indicates the default y-offset of the layer.
DefaultRotateAngle	Specifies the default angle to rotate the layer.
Foreground	Gets access to the layer's foreground object.
Grayscale	Returns or sets a value that indicates that indicates percent to convert the layer to grayscale.
Height	Specifies the expression relative to the view, to determine the height to show the current layer on the control.

Idem	Ensures that the layer's offset and rotation-angle is equal for all idem layers (separated by comma character).
Index	Indicates the index of the layer.
Key	Retrieves or sets the layer's key.
LayerClipToAlpha	Returns or sets a value that indicates the value of the alpha channel to be included in the LayerClipTo region.
LayerToClientX	Converts the x-position of the layer to control's client x-position.
LayerToClientY	Converts the x-position of the layer to control's client x-position.
Left	Specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
OffsetToValue	Specifies the expression to convert the offsetx,offsety to value.
OffsetX	Gets or sets a value that indicates x-offset of the layer.
OffsetXValid	Validates the x-offset value of the layer
OffsetY	Gets or sets a value that indicates y-offset of the layer.
OffsetYValid	Validates the y-offset value of the layer
OnDrag	Indicates the action to be performed when the user drags the layer.
Position	Retrieves or sets a value that indicates the position/z-order of the layer in the control.
RotamoveCenterX	Specifies the x-position of the layer's center, while the layer's drag operation is exDoRotamove.
RotamoveCenterY	Specifies the y-position of the layer's center, while the layer's drag operation is exDoRotamove.
RotamoveOffsetX	Specifies the x-offset of the layer, while the layer's drag operation is exDoRotamove.
RotamoveOffsetY	Specifies the y-offset of the layer, while the layer's drag operation is exDoRotamove.
RotateAngle	Specifies the angle to rotate the layer.
RotateAngleToValue	Specifies the expression to convert the rotating angle to value.
RotateAngleValid	Validates the rotation angle of the layer.
	Indicates the index of the layer the rotation is around. If -1,

RotateCenterLayer	the rotation is relative to the current layer.
RotateCenterX	Indicates the expression that determines the x-origin of the rotation point relative to the RotateCenterLayer layer.
RotateCenterY	Indicates the expression that determines the y-origin of the rotation point relative to the RotateCenterLayer layer.
RotateClip	Specifies whether the layer's clipping region is rotated once the layer is rotated.
RotateType	Returns or sets a value that indicates whether the layer's rotation is performed fast, by shearing (high quality rotation), ...
Selectable	Returns or sets a value that indicates whether the layer is selectable.
ShowHandCursor	Returns or sets a value that indicates whether the hand cursor is shown when it hovers a visible / selectable / draggable layer.
ToolTip	Gets or sets a value (tooltip) that's displayed once the cursor hovers the layer.
ToolTipTitle	Gets or sets a value (title) that's displayed once the cursor hovers the layer.
Top	Specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
Transparency	Gets or sets a value that indicates percent of the transparency to display the layer.
UserData	Indicates any extra data associated with the layer.
Value	Indicates the object's value.
ValueToOffsetX	Specifies the expression to convert the value to x-offset.
ValueToOffsetY	Specifies the expression to convert the value to y-offset.
ValueToRotateAngle	Specifies the expression to convert the value to rotating angle
Visible	Retrieves or sets a value indicating whether the layer is visible or hidden.
Width	Specifies the expression relative to the view, to determine the width to show the current layer on the control.

property Layer.Background as Background

Gets access to the layer's background object.

Type	Description
Background	A Background object that indicates the layer's background.

The Background property gets access to the layer's background object. The [Background](#) object holds pictures to be shown on the layer's background. The Layer's background can display unlimited graphics of different sizes and positions. For instance, the [Picture](#) property of the Background specifies the picture to be shown on the layer's background. Use the [ExtraPicture](#) property to assign a new picture on the same location. The [Color](#) property indicates the layer's color object, so you can apply a solid color on the layer's background.

The following screen shot shows pictures on each layer's background:

property Layer.Brightness(Channel as ColorAdjustmentChannelEnum) as Long

Specifies the percent of brightness to apply to the layer.

Type	Description
Channel as ColorAdjustmentChannelEnum	A ColorAdjustmentChannelEnum expression that specifies the channel to be changed.
Long	A Long expression that specifies the percent of brightness / color to apply to the layer.

By default, the Brightness on all channels is 50%, which indicates that no effect is applied to the layer. The Brightness specifies the percent of brightness to apply to the layer. Use the [DefaultLayer\(exDefLayerBrightness...\)](#) property to specify the default value for the Brightness(exAllChannels...), before adding any layer. The Brightness / [Contrast](#) properties can be used to change the percent of specified color to be applied on the layer. You can use the [Grayscale](#) property to show the entire layer in gray scale (disable state).

The following screen shot shows the layer, with all Brightness properties on 50% (default):

The following screen shot shows the layer, with more red, Brightness(exAllChannels) = 0,Brightness(exRedChannel) = 75:

By default, the [AllowSmoothChange](#) property is `exLayerTransparency | exLayerBrightness | exLayerContrast`. Use the `AllowSmoothChange` property to disable changing gradually any brightness / contrast or the transparency, of the layer. For instance, a gradually change means that you can change the layer's transparency from 0 to 50 in a short time, with intermediate values (smooth change).

The `AllowSmoothChange` property changes gradually one / or more properties like follow:

- `Brightness`, Specifies the percent of brightness to apply to the layer.
- [Contrast](#), Specifies the percent of contrast to apply to the layer.
- [Transparency](#), Gets or sets a value that indicates percent of the transparency to display the layer.

The [MouseIn](#) / [MouseOut](#) event notifies your application when the cursor is entering / leaving the layer. The [MouseMove](#) event is generated continually as the mouse pointer moves across objects. The `AllowSmoothChange` property specifies the properties of the layers that support smooth change. For instance, you can use the `MouseIn` / `MouseOut` event to change gradually the brightness / contrast or the transparency, of the layer, while the `AllowSmoothChange` property is not `exSmoothChangeless`.

property Layer.Clip as Clip

Gets access to the layer's clip object.

Type	Description
Clip	A Clip object that helps you to clip the current layer.

The Clip property accesses the layer's Clip object. The Clip object defines the clipping you can apply to any layer on the control. The Clipping support include intersection of any of rectangle, round rectangle, ellipse, pie, picture mask, polygon, and so on. The [RotateClip](#) property specifies whether the layer's clipping region is rotated once the layer is rotated.

Any of the following properties (or combination of them) can be used to do the clipping:

- [Ellipse](#), clips the layer as a ellipse / circle
- [Picture](#), clips the layer using a picture as a mask
- [Pie](#), clips the layer as a arc / pie
- [Polygon](#), clips the layer giving the points that define a polygon, triangle, rectangle, and so on
- [Rectangle](#), clips the layer giving a rectangle
- [RoundRectangle](#), clips the layer giving a round rectangle

The [Type](#) property specifies the type of the clipping the current layer supports. For instance LayerClipTypeEnum.exLayerClipPie | LayerClipTypeEnum.exLayerClipRectangle specifies that a pie and rectangle clippings are combined together. The [Value](#) property of the Clip indicates the value to be applied to the current clipping object to define a new shape based on the value. For instance, you may want to define a value from 0 to 100, for a circle, and for 50 to show a half of circle, for 25, a quarter of circle (pie), and so on.

Having the following layer:

By clipping, we can get something like follows:

and if we display the entire gauge here's what we get:

property Layer.Contrast(Channel as ColorAdjustmentChannelEnum) as Long

Specifies the percent of contrast to apply to the layer.

Type	Description
Channel as ColorAdjustmentChannelEnum	A ColorAdjustmentChannelEnum expression that specifies the channel to be changed.
Long	A Long expression that specifies the percent of contrast / color to apply to the layer.

By default, the Contrast on all channels is 50%, which indicates that no effect is applied to the layer. The Contrast property specifies the percent of contrast to apply to the layer. Use the [DefaultLayer\(exDefLayerContrast...\)](#) property to specify the default value for the Contrast(exAllChannels...), before adding any layer. The [Brightness](#) / Contrast properties can be used to change the percent of specified color to be applied on the layer. You can use the [Grayscale](#) property to show the entire layer in gray scale (disable state).

The following screen shot shows the layer, with all Contrast properties on 50% (default):

The following screen shot shows the layer, with more red, Contrast(exAllChannels) = 0, Contrast(exRedChannel) = 75:

By default, the [AllowSmoothChange](#) property is `exLayerTransparency | exLayerBrightness | exLayerContrast`. Use the `AllowSmoothChange` property to disable changing gradually any brightness / contrast or the transparency, of the layer. For instance, a gradually change means that you can change the layer's transparency from 0 to 50 in a short time, with intermediate values (smooth change).

The `AllowSmoothChange` property changes gradually one / or more properties like follow:

- [Brightness](#), Specifies the percent of brightness to apply to the layer.
- `Contrast`, Specifies the percent of contrast to apply to the layer.
- [Transparency](#), Gets or sets a value that indicates percent of the transparency to display the layer.

The [MouseIn](#) / [MouseOut](#) event notifies your application when the cursor is entering / leaving the layer. The [MouseMove](#) event is generated continually as the mouse pointer moves across objects. The `AllowSmoothChange` property specifies the properties of the layers that support smooth change. For instance, you can use the `MouseIn` / `MouseOut` event to change gradually the brightness / contrast or the transparency, of the layer, while the `AllowSmoothChange` property is not `exSmoothChangeless`.

property Layer.DefaultOffsetX as Long

Gets or sets a value that indicates the default x-offset of the layer.

Type	Description
Long	A Long expression that defines the default x-offset of the layer.

By default, the DefaultOffsetX property is 0. The DefaultOffsetX property gets or sets a value that indicates the default x-offset of the layer. You can use the DefaultOffsetX / DefaultOffsetX properties to move the layer to a different position, which could be the initial position. Use the [DefaultLayer\(exDefLayerDefaultOffsetX\)](#) property to specify the default value for the DefaultOffsetX, before adding any layer.

The following picture shows the position/size properties of the Layer, relative to the view / control:

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- `DefaultOffsetX`, gets or sets a value that indicates the default x-offset of the layer.
- [`OffsetX`](#), gets or sets a value that indicates x-offset of the layer.
- [`OffsetXValid`](#), validates the x-offset value of the layer.
- [`Value`](#) and [`ValueToOffsetX`](#) specifies the expression to convert the value to x-offset.
- [`DefaultOffsetY`](#), gets or sets a value that indicates the default y-offset of the layer.
- [`OffsetY`](#), gets or sets a value that indicates y-offset of the layer.
- [`OffsetYValid`](#), validates the y-offset value of the layer.
- [`Value`](#) and [`ValueToOffsetY`](#) specifies the expression to convert the value to y-offset.

The following properties can be used to move / resize the **picture** on the layer's background:

- [`DisplayAs`](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [`Left`](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [`Top`](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [`Width`](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [`Height`](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

property Layer.DefaultOffsetY as Long

Gets or sets a value that indicates the default y-offset of the layer.

Type	Description
Long	A Long expression that defines the default y-offset of the layer.

By default, the DefaultOffsetY property is 0. The DefaultOffsetY property gets or sets a value that indicates the default y-offset of the layer. You can use the DefaultOffsetX / DefaultOffsetY properties to move the layer to a different position, which could be the initial position. Use the [DefaultLayer\(exDefLayerDefaultOffsetY\)](#) property to specify the default value for the DefaultOffsetY, before adding any layer.

The following picture shows the position/size properties of the Layer, relative to the view / control:

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [DefaultOffsetX](#), gets or sets a value that indicates the default x-offset of the layer.
- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetXValid](#), validates the x-offset value of the layer.
- [Value](#) and [ValueToOffsetX](#) specifies the expression to convert the value to x-offset.
- [DefaultOffsetY](#), gets or sets a value that indicates the default y-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.
- [OffsetYValid](#), validates the y-offset value of the layer.
- [Value](#) and [ValueToOffsetY](#) specifies the expression to convert the value to y-offset.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

property Layer.DefaultRotateAngle as Double

Specifies the default angle to rotate the layer.

Type	Description
Double	A Double expression that specifies the default angle to rotate the layer, in degree.

By default, the DefaultRotateAngle property is 0 degree (which indicates that the layer is shown as it is). The DefaultRotateAngle property specifies the default angle to rotate the layer. For instance, you can use the DefaultRotateAngle property to show the current layer in a different position, as an initial view. Use the [DefaultLayer\(exDefLayerDefaultRotateAngle\)](#) property to specify the default value for the DefaultRotateAngle property, before adding any layer. The [RotateType](#) property specifies whether the layer's rotation is performed fast, by shearing (high quality rotation), ... Change the [Debug](#) property of the [DragInfo](#) during the [DragStart](#) event to debug the rotation angles.

The following picture shows the rotation properties of the Layer, relative to the [RotateCenterLayer](#) layer:

Any of the following properties can be used to rotate the layer:

- DefaultRotateAngle, specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the [RotateCenterLayer](#) layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the [RotateCenterLayer](#) layer.

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is exDoRotamove:

- [RotamoveCenterX](#), specifies the x-position of the layer's center.
- [RotamoveCenterY](#), specifies the y-position of the layer's center.
- [RotamoveOffsetX](#), specifies the x-offset of the layer.
- [RotamoveOffsetY](#), specifies the y-offset of the layer.

property Layer.Foreground as Foreground

Gets access to the layer's foreground object.

Type	Description
Foreground	A Foreground object that holds the HTML captions to be shown on the layer's foreground.

The Foreground object holds HTML captions to be shown on the layer's foreground. The [Background](#) object holds pictures to be shown on the layer's background. The Layer's foreground can display unlimited HTML captions of different sizes and positions. The [Caption](#) property specifies the caption on the layer. The [ExtraCaption](#) property assigns a new HTML caption on the layer's foreground. The [Color](#) property specifies the layer's foreground color.

The following screen shot shows all layer's background with a semi-transparent color, to highlight the layer's foreground:

property Layer.Grayscale as Long

Returns or sets a value that indicates whether the layer is show as grayscale.

Type	Description
Long	A long expression that indicates the percent to convert the layer into grayscale (value between 0 and 100)

By default, the Grayscale property is 0, so the layer is shown normal (enabled). You can use the Grayscale property to show the entire layer in gray scale (disable state). Use the [DefaultLayer\(exDefLayerGrayscale\)](#) property to specify the default value for the Grayscale property, before adding any layer. The [Brightness](#) / [Contrast](#) properties can be used to change the percent of specified color to be applied on the layer. The [Selectable](#) property specifies whether the user can select the layer at runtime. For instance, you can simulate a disabled layer by changing the layer's Grayscale property on True, and setting the layer's Selectable property on False.

The following screen shot shows the layer, with Grayscale property on False (by default):

The following screen shot shows the layer, with Grayscale property on True:

property Layer.Height as String

Specifies the expression relative to the view, to determine the height to show the current layer on the control.

Type	Description
String	A String value that specifies the expression relative to the view, to determine the height to show the current layer on the control.

By default, the Height property is "height". If the Height property is empty, missing or invalid, it is considered "height". If valid, the value of evaluating the Height property indicates the height of the layer as shown in the picture bellow. Use the [DefaultLayer\(exDefLayerHeight\)](#) property to specify the default value for the Height property, before adding any layer. The [LayerAutoSize](#) property resizes all layers based on the picture of the first layer.

For instance:

- "0" indicates that the layer's height is 0
- "height / 2", half of the view or center of the control's view
- "height - 64", 64 pixels to the bottom side of the control's view

The Height property supports the following keywords:

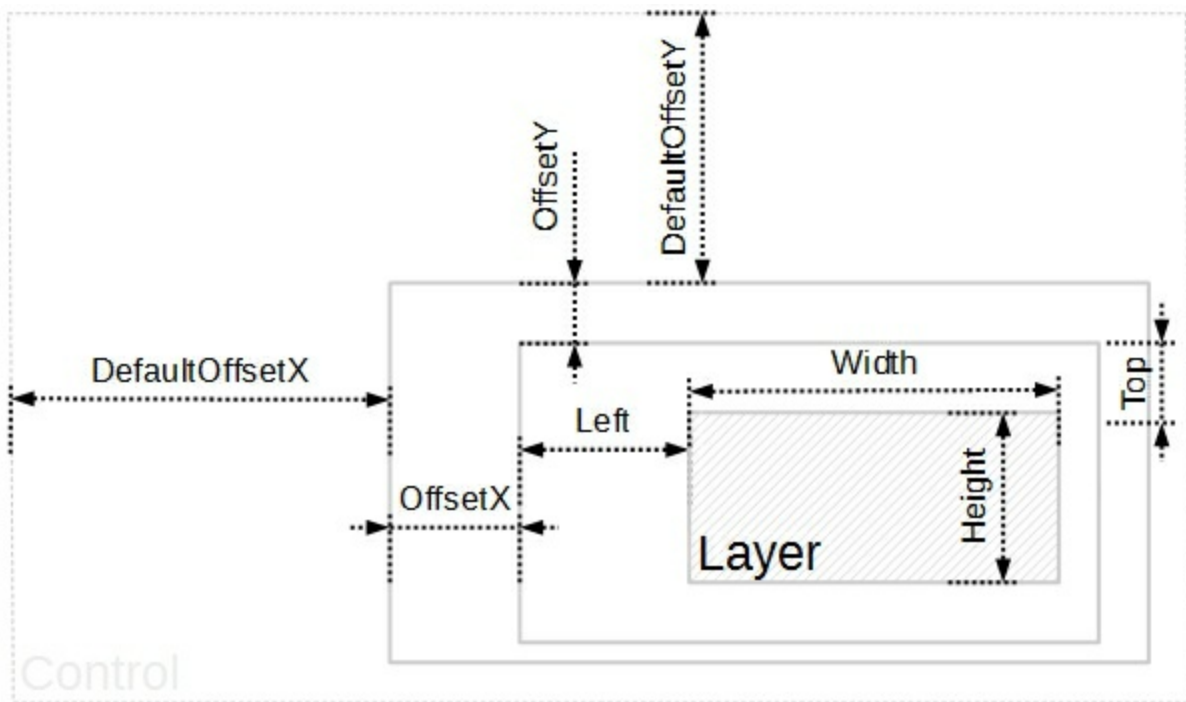

- **width** keyword specifies the width in pixels of the control's view
- **height** keyword specifies the height in pixels of the control's view

Also, this property supports all constants, operators and functions defined [here](#).

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- Height, specifies the expression relative to the view, to determine the height to show the current layer on the control.

The following picture shows the position/size properties of the Layer, relative to the view / control:

You can use the following properties to offset the view (background + foreground) inside the layer:

- [DefaultOffsetX](#), gets or sets a value that indicates the default x-offset of the layer.
- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetXValid](#), validates the x-offset value of the layer.
- [Value](#) and [ValueToOffsetX](#) specifies the expression to convert the value to x-offset.
- [DefaultOffsetY](#), gets or sets a value that indicates the default y-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.
- [OffsetYValid](#), validates the y-offset value of the layer.
- [Value](#) and [ValueToOffsetY](#) specifies the expression to convert the value to y-offset.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

property Layer.Idem as Variant

Ensures that the layer's offset and rotation-angle is equal for all idem layers (separated by comma character).

Type	Description
Variant	A long expression that specifies the index of the layer idem with current layer, a string expression that specifies the key of the layer idem with the current layer, or a list of keys separated by comma character. For instance, Idem = "0,1" indicates that the current layer's rotation-angle and offset are always the same as layers with the index 0 and 1

By default, the Idem property is empty, which indicates hat has no effect. You can use the Idem property to rotate or move multiple layers once user drags a layer. The [Item](#) property of the Layers collection accesses a Layer giving its index or key. The [Key](#) property retrieves or sets the layer's key. The [Index](#) property is read-only and zero-based, which indicates that the layer with the Index property 0, it is the first layer, while the layer with the index [Count](#) - 1, is the last layer in the control (in z-order).

property Layer.Index as Long

Indicates the index of the layer.

Type	Description
Long	A Long expression that specifies the index of the layer.

By default, the Index property is automatically updated by the control, as soon as the user adds / removes layers to the control. The Index property is read-only and zero-based, which indicates that the layer with the Index property 0, it is the first layer, while the layer with the index [Count](#) - 1, is the last layer in the control (in z-order). The [Key](#) property retrieves or sets the layer's key. The [Item](#) property of the Layers collection accesses a Layer giving its index or key. The [LayerFromPoint](#) retrieves the index of the layer from the point (only visible and selectable objects are included).

property Layer.Key as Variant

Retrieves or sets the layer's key.

Type	Description
Variant	A VARIANT expression that specifies the key to identify the layer.

By default, the Key property is empty. The Key property retrieves or sets the layer's key. The [Index](#) property is read-only and zero-based, which indicates that the layer with the Index property 0, it is the first layer, while the layer with the index [Count](#) - 1, is the last layer in the control (in z-order). The [Item](#) property of the Layers collection accesses a Layer giving its index or key. The [LayerFromPoint](#) retrieves the index of the layer from the point (only visible and selectable objects are included).

property Layer.LayerClipToAlpha as Long

Returns or sets a value that indicates the value of the alpha channel to be included in the LayerClipTo region.

Type	Description
Long	A Long expression that returns or sets a value that indicates the value of the alpha channel to be included in the LayerClipTo region.

By default, the LayerClipToAlpha property is 0, which indicates that only pixels of the layer that has 0 on the alpha channel (transparent pixels) defines the transparent region, and so the clipping region. The LayerClipToAlpha property property of the Layer object, returns or sets a value that indicates the value of the alpha channel to be included in the LayerClipTo region. In other words, the value from 0 to LayerClipToAlpha defines transparent pixels, and the rest defines the opaque pixels to be included in the clipping region. So based on the layer's picture, you can change the LayerClipToAlpha property for a better look of your widget. The [LayerClipTo](#) property specifies the index of the layer that clips the entire control to. The [LayerClipToParent](#) property indicates if the [LayerClipTo](#) method clips the control itself, parent or the owner of the control.

"I would like to put the control on a form, then make the form transparent so the control appears on the desktop with just the images contained in the layers visible. For example, take a clock example and make the control background and the form transparent, and you have a working clock widget."

The control support transparent form, or in other words, displaying the control's itself without its form behind. In order to make your eXGauge control to display a widget, (no form behind or form transparent), you need to use the following properties:

- [LayerClipTo](#) property of the control, specifies the index of the layer that clips the entire control to. By default, the LayerClipTo property is -1, which indicates that no clipping is supported. So, one of the layers that composes your widget must be specified as the widget's background, and so, the entire view of the control is clipped to region defined by the clipping layer (LayerClipTo). The LayerClipTo property may refer to any layer, visible or hidden, which includes a picture or a clipping object (Clip property).
- **Layer.LayerClipToAlpha** property of the Layer object, returns or sets a value that indicates the value of the alpha channel to be included in the LayerClipTo region. By default, the LayerClipToAlpha property is 0, which indicates that only pixels of the layer that has 0 on the alpha channel (transparent pixels) defines the transparent region, and so the clipping region. In other words, the value from 0 to LayerClipToAlpha defines transparent pixels, and the rest defines the opaque pixels to be included in the clipping region. Sobased on the layer's picture, you can change the LayerClipToAlpha property

for a better look of your widget.

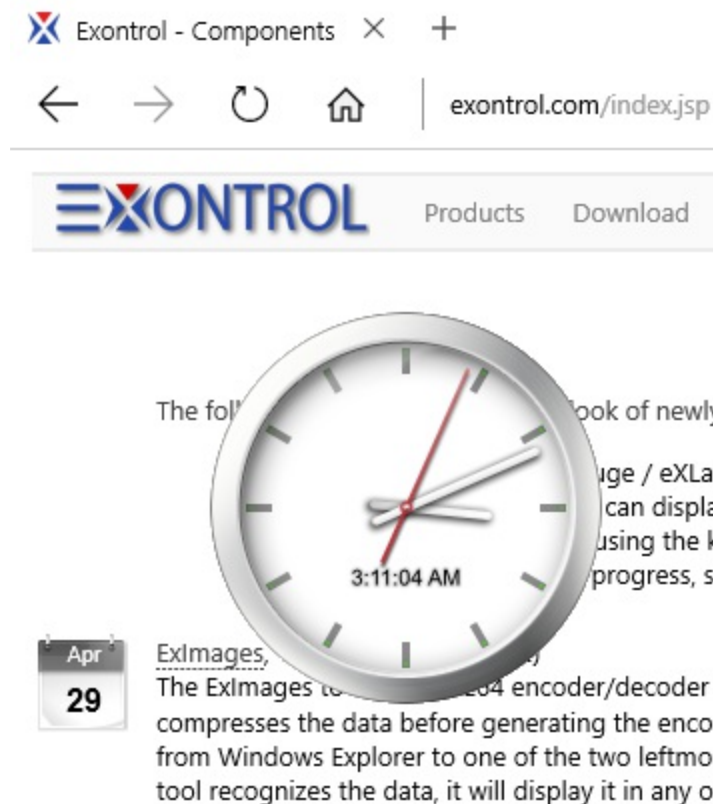

- **LayerClipToParent** property of the control, indicates if the LayerClipTo method clips the control itself, parent or the owner of the control. By default, the LayerClipToParent property is exLayerUpdateControl, which indicates that the control's itself is clipped relative to its form that hosts it. Change the LayerClipToParent property to exLayerUpdateScreen, or exLayerUpdateParent, and so the clipping region is applied to its form/dialog/parent window.

The following VB sample defines the control as a widget:

```
With Gauge1
    .LayerClipTo = 0
    .LayerClipToParent = exLayerUpdateScreen
End With
```

The sample defines the layer with the Index 0, as being the clipping layer. The setup installs the C:\Program Files\Exontrol\ExGauge\Sample\VB\Clock-Widget-Region that shows all these working.

The following screen shot shows the control on a transparent form:

The following screen shot shows the control on an opaque form:

tool recognizes the data, it will display it in any c

property Layer.LayerToClientX (X as Variant, Y as Variant) as Long

Converts the x-position of the layer to control's client x-position.

Type	Description
X as Variant	A Lone expression that specifies the x-position of the point within the layer
Y as Variant	A Lone expression that specifies the y-position of the point within the layer
Long	A Long expression that specifies the x-position of the point on the control's view that's equivalent of the point on the layer.

The LayerToClientX / [LayerToClientY](#) converts the (x,y)-point on the layer to control's view point. The LayerToClientX / [LayerToClientY](#) properties translate a point from the layer (as it is moved or rotated) to the control's view. For instance, you can display the current value of the control on the knob you are rotating. The [RotamoveCenterX](#) / [RotamoveCenterY](#) specifies the (x,y)-position of the layer's center, while the layer's drag operation is exDoRotamove. The [OnDrag](#) property indicates the action to be performed when the user drags the layer.

Any of the following properties can be used to display a HTML caption:

- [Caption](#) property specifies the caption to be shown on the control's foreground.
- [ExtraCaption](#) property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

The following sample shows how you can use the `LayerToClientX` / [LayerToClientY](#) properties to display the layer's value on the knob:

VBA (MS Access, Excell...)

property Layer.LayerToClientY (X as Variant, Y as Variant) as Long

Converts the x-position of the layer to control's client x-position.

Type	Description
X as Variant	A Lone expression that specifies the x-position of the point within the layer
Y as Variant	A Lone expression that specifies the y-position of the point within the layer
Long	A Long expression that specifies the y-position of the point on the control's view that's equivalent of the point on the layer.

The [LayerToClientX](#) / LayerToClientY converts the (x,y)-point on the layer to control's view point. The [LayerToClientX](#) / LayerToClientY properties translate a point from the layer (as it is moved or rotated) to the control's view. For instance, you can display the current value of the control on the knob you are rotating. The [RotamoveCenterX](#) / [RotamoveCenterY](#) specifies the (x,y)-position of the layer's center, while the layer's drag operation is `exDoRotamove`. The [OnDrag](#) property indicates the action to be performed when the user drags the layer.

Any of the following properties can be used to display a HTML caption:

- [Caption](#) property specifies the caption to be shown on the control's foreground.
- [ExtraCaption](#) property specifies any extra caption to be shown on the control's foreground.
- [Foreground.Caption](#) specifies the caption to be shown on the layer's foreground.
- [Foreground.ExtraCaption](#) specifies any extra caption to be shown on the layer's foreground.

The following sample shows how you can use the `LayerToClientX` / [LayerToClientY](#) properties to display the layer's value on the knob:

VBA (MS Access, Excell...)

property Layer.Left as String

Specifies the expression relative to the view, to determine the x-position to show the current layer on the control.

Type	Description
String	A String expression expression relative to the view, to determine the x-position to show the current layer on the control.

By default, the Left property is "0". If the Left property is empty, missing or invalid, it is considered "0". If valid, the value of evaluating the Left property indicates the left position of the layer as shown in the picture bellow. Use the [DefaultLayer\(exDefLayerLeft\)](#) property to specify the default value for the Left property, before adding any layer.

For instance:

- "0" indicates the left side of the control's view
- "width / 2", half of the view or center of the control's view
- "width - 64", 64 pixels to the right side of the control's view

The Left property supports the following keywords:

- **width** keyword specifies the width in pixels of the control's view
- **height** keyword specifies the height in pixels of the control's view

Also, this property supports all constants, operators and functions defined [here](#).

The following properties determines the position / size / offset of the **layer**:

- Left, specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

The following picture shows the position/size properties of the Layer, relative to the view / control:

You can use the following properties to offset the view (background + foreground) inside the layer:

- [DefaultOffsetX](#), gets or sets a value that indicates the default x-offset of the layer.
- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetXValid](#), validates the x-offset value of the layer.
- [Value](#) and [ValueToOffsetX](#) specifies the expression to convert the value to x-offset.
- [DefaultOffsetY](#), gets or sets a value that indicates the default y-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.
- [OffsetYValid](#), validates the y-offset value of the layer.
- [Value](#) and [ValueToOffsetY](#) specifies the expression to convert the value to y-offset.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

property Layer.OffsetToValue as String

Specifies the expression to convert the offsetx,offsety to value.

Type	Description
String	A String value that specifies the expression to convert the offsetx,offsety to value.

By default, the OffsetToValue property is empty. If the OffsetToValue property is empty, missing or invalid, it has no effect. If the OffsetToValue property is valid, the result of evaluation of the OffsetToValue property indicates the layer's [Value](#) property. The [ValueToOffsetX](#) / [ValueToOffsetY](#) property converts the value back to an offset. Use the [DefaultLayer\(exDefLayerOffsetToValue\)](#) property to specify the default value for the OffsetToValue property, before adding the layer.

For instance:

- "0", specifies that the layer's value is always 0 no matter of the offset of the layer
- "value = 0 ? 0 : 1", equivalent with "offsetx = 0 ? 0 : 1" indicates that if the layer's OffsetX is 0, the value is 0 else it is one
- "offsety = 0 ? 0 : 1", indicates that if the layer's OffsetY is 0, the value is 0 else it is one

The OffsetToValue property supports the following keywords:

- **value** or **offsetx** keyword indicates the layer's [OffsetX](#) property
- **offsety** keyword indicates the layer's [OffsetY](#) property

Also, this property supports all constants, operators and functions defined [here](#).

The [Value](#) property indicates the **value** keyword in the following properties:

- [ValueToOffsetX](#), Specifies the expression to convert the value to x-offset. The layer's [OffsetX](#) property is the result of evaluating the [ValueToOffsetX](#) expression, while the [OnDrag](#) property is **exDoMove**. The OffsetToValue converts the current offset to a value.
- [ValueToOffsetY](#), Specifies the expression to convert the value to y-offset. The layer's [OffsetY](#) property is the result of evaluating the [ValueToOffsetY](#) expression, while the [OnDrag](#) property is exDoMove. The OffsetToValue converts the current offset to a value.
- [ValueToRotateAngle](#), Specifies the expression to convert the value to rotating angle. The layer's [RotateAngle](#) property is the result of evaluating the [ValueToRotateAngle](#) expression, while the [OnDrag](#) property is exDoRotate or exDoRotamove. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The Value property works in association with the layer's [OnDrag](#) property like follows:

- If the [OnDrag](#) property is **exDoMove**, evaluating the [ValueToOffsetX](#) property indicates the layer's [OffsetX](#) property.
- If the [OnDrag](#) property is **exDoMove**, evaluating the [ValueToOffsetY](#) property indicates the layer's [OffsetY](#) property.
- If the [OnDrag](#) property is **exDoRotate** or **exDoRotamove**, evaluating the [ValueToRotateAngle](#) property indicates the layer's [RotateAngle](#) property.

property Layer.OffsetX as Long

Gets or sets a value that indicates x-offset of the layer.

Type	Description
Long	A Long expression that indicates x-offset of the layer.

By default, the OffsetX / OffsetY property is 0. The OffsetX / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [OffsetXValid](#) / [OffsetYValid](#) property to validate the (x,y)-position of the layer. The [Value](#) property associates a value to a layer. The [ValueToOffsetX](#) property specifies the expression to convert the value to x-offset. The [ValueToOffsetY](#) property specifies the expression to convert the value to y-offset. For instance, you can use the OffsetYValid property on "0", and so no vertical movement is allowed for the current layer. Use the [DefaultLayer\(exDefLayerOffsetX\)](#) property to specify the default value for the OffsetX, before adding any layer. The [Change](#) event occurs when the layer's OffsetX property is changed. The [DragStart](#) / [Drag](#) / [DragEnd](#) events notify your application when a layer is dragged. The layer's [RotamoveOffsetX](#) / [RotamoveOffsetY](#) property indicates the current (x,y) position of the layer, while the [OnDrag](#) property is exDoRotamove.

The following picture shows the position/size properties of the Layer, relative to the view / control:

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show

the current layer on the control.

- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [DefaultOffsetX](#), gets or sets a value that indicates the default x-offset of the layer.
- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetXValid](#), validates the x-offset value of the layer.
- [Value](#) and [ValueToOffsetX](#) specifies the expression to convert the value to x-offset
- [DefaultOffsetY](#), gets or sets a value that indicates the default y-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.
- [OffsetYValid](#), validates the y-offset value of the layer.
- [Value](#) and [ValueToOffsetY](#) specifies the expression to convert the value to y-offset.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

property Layer.OffsetXValid as String

Validates the x-offset value of the layer

Type	Description
String	A String expression that validates the x-offset value of the layer. The result of evaluating the expression indicates the newly OffsetX value.

By default, the [OffsetXValid](#) / [OffsetYValid](#) property is empty. The [OffsetXValid](#) / [OffsetYValid](#) property has no effect if it is empty, missing or invalid. If the [OffsetXValid](#) / [OffsetYValid](#) property is valid expression, the value of [OffsetX](#) property always matches [OffsetXValid](#) expression. In other words, the [OffsetXValid](#) validates the x-position of the layer. For instance, you can use the [OffsetXValid](#) / [OffsetYValid](#) expression to specify a range of values to allow the [OffsetX](#) / [OffsetY](#) properties. Use the [DefaultLayer\(exDefLayerOffsetXValid\)](#) property to specify the default value for the [OffsetXValid](#) property, before adding any layer.

The [OffsetX](#) / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [Value](#) property associates a value to a layer. The [ValueToOffsetX](#) property specifies the expression to convert the value to x-offset. The [ValueToOffsetY](#) property specifies the expression to convert the value to y-offset. For instance, you can use the [OffsetYValid](#) property on "0", and so no vertical movement is allowed for the current layer. Use the [DefaultLayer\(exDefLayerOffsetX\)](#) property to specify the default value for the [OffsetX](#), before adding any layer. The [Change](#) event occurs when the layer's [OffsetX](#) property is changed. The [DragStart](#) / [Drag](#) / [DragEnd](#) events notify your application when a layer is dragged.

For instance:

- "0", indicates that no horizontal movement is allowed, or in other words, [OffsetX](#) is always 0.
- "16 * int(value / 16)", specifies that only multiply of 16 is allowed for [OffsetX](#) property (grid movement)
- "value = 0 ? 0 : (value < 0 ? -100 : +100)", indicates that valid values for [OffsetX](#) property is -100, 0 and +100 (discrete movement)
- "value MIN -64 MAX 64", indicates that values of [OffsetX](#) property are between -64 and +64 (range movement)
- "y" indicates that [OffsetX](#) property is always the same as [OffsetY](#) property (diagonal movement)

The [OffsetXValid](#) property supports the following keywords:

- **value** keyword indicates the current value of [OffsetX](#) property (the value to validate)

- **y** keyword specifies the current value of the [OffsetY](#) property

Also, this property supports all constants, operators and functions defined [here](#).

The following picture shows the position/size properties of the Layer, relative to the view / control:

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [DefaultOffsetX](#), gets or sets a value that indicates the default x-offset of the layer.
- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetXValid](#), validates the x-offset value of the layer.
- [Value](#) and [ValueToOffsetX](#) specifies the expression to convert the value to x-offset.
- [DefaultOffsetY](#), gets or sets a value that indicates the default y-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.
- [OffsetYValid](#), validates the y-offset value of the layer.

- [Value](#) and [ValueToOffsetY](#) specifies the expression to convert the value to y-offset.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

property Layer.OffsetY as Long

Gets or sets a value that indicates y-offset of the layer.

Type	Description
Long	A Long expression that indicates y-offset of the layer.

By default, the OffsetX / OffsetY property is 0. The [OffsetX](#) / OffsetY property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [OffsetXValid](#) / [OffsetYValid](#) property to validate the (x,y)-position of the layer. The [Value](#) property associates a value to a layer. The [ValueToOffsetX](#) property specifies the expression to convert the value to x-offset. The [ValueToOffsetY](#) property specifies the expression to convert the value to y-offset. For instance, you can use the OffsetXValid property on "0", and so no horizontal movement is allowed for the current layer. Use the [DefaultLayer\(exDefLayerOffsetY\)](#) property to specify the default value for the OffsetY, before adding any layer. The [Change](#) event occurs when the layer's OffsetY property is changed. The [DragStart](#) / [Drag](#) / [DragEnd](#) events notify your application when a layer is dragged. The layer's [RotamoveOffsetX](#) / [RotamoveOffsetY](#) property indicates the current (x,y) position of the layer, while the [OnDrag](#) property is exDoRotamove.

The following picture shows the position/size properties of the Layer, relative to the view / control:

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show

the current layer on the control.

- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [DefaultOffsetX](#), gets or sets a value that indicates the default x-offset of the layer.
- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetXValid](#), validates the x-offset value of the layer.
- [Value](#) and [ValueToOffsetX](#) specifies the expression to convert the value to x-offset.
- [DefaultOffsetY](#), gets or sets a value that indicates the default y-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.
- [OffsetYValid](#), validates the y-offset value of the layer.
- [Value](#) and [ValueToOffsetY](#) specifies the expression to convert the value to y-offset.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

property Layer.OffsetYValid as String

Validates the y-offset value of the layer

Type	Description
String	A String expression that validates the y-offset value of the layer. The result of evaluating the expression indicates the newly OffsetY value.

By default, the [OffsetXValid](#) / [OffsetYValid](#) property is empty. The [OffsetXValid](#) / [OffsetYValid](#) property has no effect if it is empty, missing or invalid. If the [OffsetXValid](#) / [OffsetYValid](#) property is valid expression, the value of [OffsetY](#) property always matches [OffsetYValid](#) expression. In other words, the [OffsetYValid](#) validates the y-position of the layer. For instance, you can use the [OffsetXValid](#) / [OffsetYValid](#) expression to specify a range of values to allow the [OffsetX](#) / [OffsetY](#) properties. Use the [DefaultLayer\(exDefLayerOffsetYValid\)](#) property to specify the default value for the [OffsetYValid](#) property, before adding any layer.

The [OffsetX](#) / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [Value](#) property associates a value to a layer. The [ValueToOffsetX](#) property specifies the expression to convert the value to x-offset. The [ValueToOffsetY](#) property specifies the expression to convert the value to y-offset. For instance, you can use the [OffsetYValid](#) property on "0", and so no vertical movement is allowed for the current layer. Use the [DefaultLayer\(exDefLayerOffsetX\)](#) property to specify the default value for the [OffsetX](#), before adding any layer. The [Change](#) event occurs when the layer's [OffsetX](#) property is changed. The [DragStart](#) / [Drag](#) / [DragEnd](#) events notify your application when a layer is dragged.

For instance:

- "0", indicates that no vertical movement is allowed, or in other words, [OffsetY](#) is always 0.
- "16 * int(value / 16)", specifies that only multiply of 16 is allowed for [OffsetY](#) property (grid movement)
- "value = 0 ? 0 : (value < 0 ? -100 : +100)", indicates that valid values for [OffsetY](#) property is -100, 0 and +100 (discrete movement)
- "value MIN -64 MAX 64", indicates that values of [OffsetY](#) property are between -64 and +64 (range movement)
- "x" indicates that [OffsetY](#) property is always the same as [OffsetX](#) property (diagonal movement)

The [OffsetYValid](#) property supports the following keywords:

- **value** keyword indicates the current value of [OffsetY](#) property (the value to validate)

- **x** keyword specifies the current value of the [OffsetX](#) property

Also, this property supports all constants, operators and functions defined [here](#).

The following picture shows the position/size properties of the Layer, relative to the view / control:

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [DefaultOffsetX](#), gets or sets a value that indicates the default x-offset of the layer.
- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetXValid](#), validates the x-offset value of the layer.
- [Value](#) and [ValueToOffsetX](#) specifies the expression to convert the value to x-offset.
- [DefaultOffsetY](#), gets or sets a value that indicates the default y-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.
- [OffsetYValid](#), validates the y-offset value of the layer.

- [Value](#) and [ValueToOffsetY](#) specifies the expression to convert the value to y-offset.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

property Layer.OnDrag as OnDragLayerEnum

Indicates the action to be performed when the user drags the layer.

Type	Description
OnDragLayerEnum	An OnDragLayerEnum expression that specifies the operation to perform when the user clicks and drags the layer.

By default, the OnDrag property is `exDoNothing`, so nothing is happen if the user clicks the layer. The [Change](#) event occurs when the layer's value property is changed. The [DragStart](#) / [Drag](#) / [DragEnd](#) events notify your application when a layer is dragged. The [ShowHandCursor](#) property returns or sets a value that indicates whether the hand cursor is shown when it hovers a visible / selectable / draggable layer. The [Clip](#) property gets access to the layer's clipping object. The [Value](#) property of the Layer has effect only if the OnDrag property is not `exDoNothing`. The [Selectable](#) property returns or sets a value that indicates whether the layer is selectable.

Currently, any layer supports any of the following operations:

- **exDoMove**, moves a layer, the layer's [OffsetX](#) and [OffsetY](#) indicates the current (x,y) position of the layer.
- **exDoRotate**, rotates a layer, the [RotateAngle](#) property indicates the currently rotation angle.
- **exDoRotamove**, rotates the layer by moving, the [RotateAngle](#) property indicates the currently rotation angle. In this case, the layer's [RotamoveOffsetX](#) / [RotamoveOffsetY](#) property indicates the current (x,y) position of the layer. The `exDoRotamove` operation does not actually rotate the layer's view instead it moves / rotates it relative to its center.

The control fires the drag events in the following order:

- [DragStart](#) event notifies that a layer begins to drag. You can use the DragStart event to cancel the dragging operation.
- [Drag](#) event notifies that the layer is dragging. You can use the Drag event to perform other actions, on any layer during the dragging operation.
- [DragEnd](#) event notifies that the dragging the layer ends. You can use the DragEnd event to perform other actions, on any layer when dragging operation ends.

You can use the [Debug](#) property of the DragInfo object to display debugging information during dragging.

property Layer.Position as Long

Retrieves or sets a value that indicates the position/z-order of the layer in the control.

Type	Description
Long	A Long expression that specifies the position of the layer within the layers collection.

The Position property specifies the position of the layer, in the layers collection. The [Visible](#) property shows or hides a specific layer (visible). The [Selectable](#) property returns or sets a value that indicates whether the layer is selectable. The [LayerFromPoint](#) property retrieves the layer from point that's visible and selectable. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (dragable).

property Layer.RotamoveCenterX as Long

Specifies the x-position of the layer's center, while the layer's drag operation is exDoRotamove.

Type	Description
Long	A Long expression that specifies the x-position of the layer's center

By default the RotamoveCenterX / [RotamoveCenterY](#) indicates the (x,y)-center of the layer's view. The control supports moving the layer by rotation, also called rotamove. The rotamove operation moves layer and the rotamove center pointed by RotamoveCenterX / RotamoveCenterY properties around the rotation center pointed by the [RotateCenterX](#) / [RotateCenterY](#) properties of the [RotateCenterLayer](#) layer. The [LayerToClientX](#) / [LayerToClientY](#) properties translate a point from the layer (as it is moved or rotated) to the control's view.

The center of the layer may be different than layer's view, as for instance, if you have a layer that's shows a knob in the bottom-side of the layer the RotamoveCenterX / RotamoveCenterY point is the center on the knob in the bottom-right side not in the center of the layer as you can see in the following screen shot (red cross) :

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is exDoRotamove:

- RotamoveCenterX, specifies the x-position of the layer's center (view).
- [RotamoveCenterY](#), specifies the y-position of the layer's center (view).
- [RotamoveOffsetX](#), specifies the x-offset of the layer.
- [RotamoveOffsetY](#), specifies the y-offset of the layer.

The following picture shows the rotamove properties of the Layer, relative to the [RotateCenterLayer](#) layer:

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the [RotateCenterLayer](#) layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the [RotateCenterLayer](#) layer.

property Layer.RotamoveCenterY as Long

Specifies the y-position of the layer's center, while the layer's drag operation is exDoRotamove.

Type	Description
Long	A Long expression that specifies the x-position of the layer's center

By default the [RotamoveCenterX](#) / RotamoveCenterY indicates the (x,y)-center of the layer's view. The control supports moving the layer by rotation, also called rotamove. The rotamove operation moves layer and the rotamove center pointed by RotamoveCenterX / RotamoveCenterY properties around the rotation center pointed by the [RotateCenterX](#) / [RotateCenterY](#) properties of the [RotateCenterLayer](#) layer. The [LayerToClientX](#) / [LayerToClientY](#) properties translate a point from the layer (as it is moved or rotated) to the control's view.

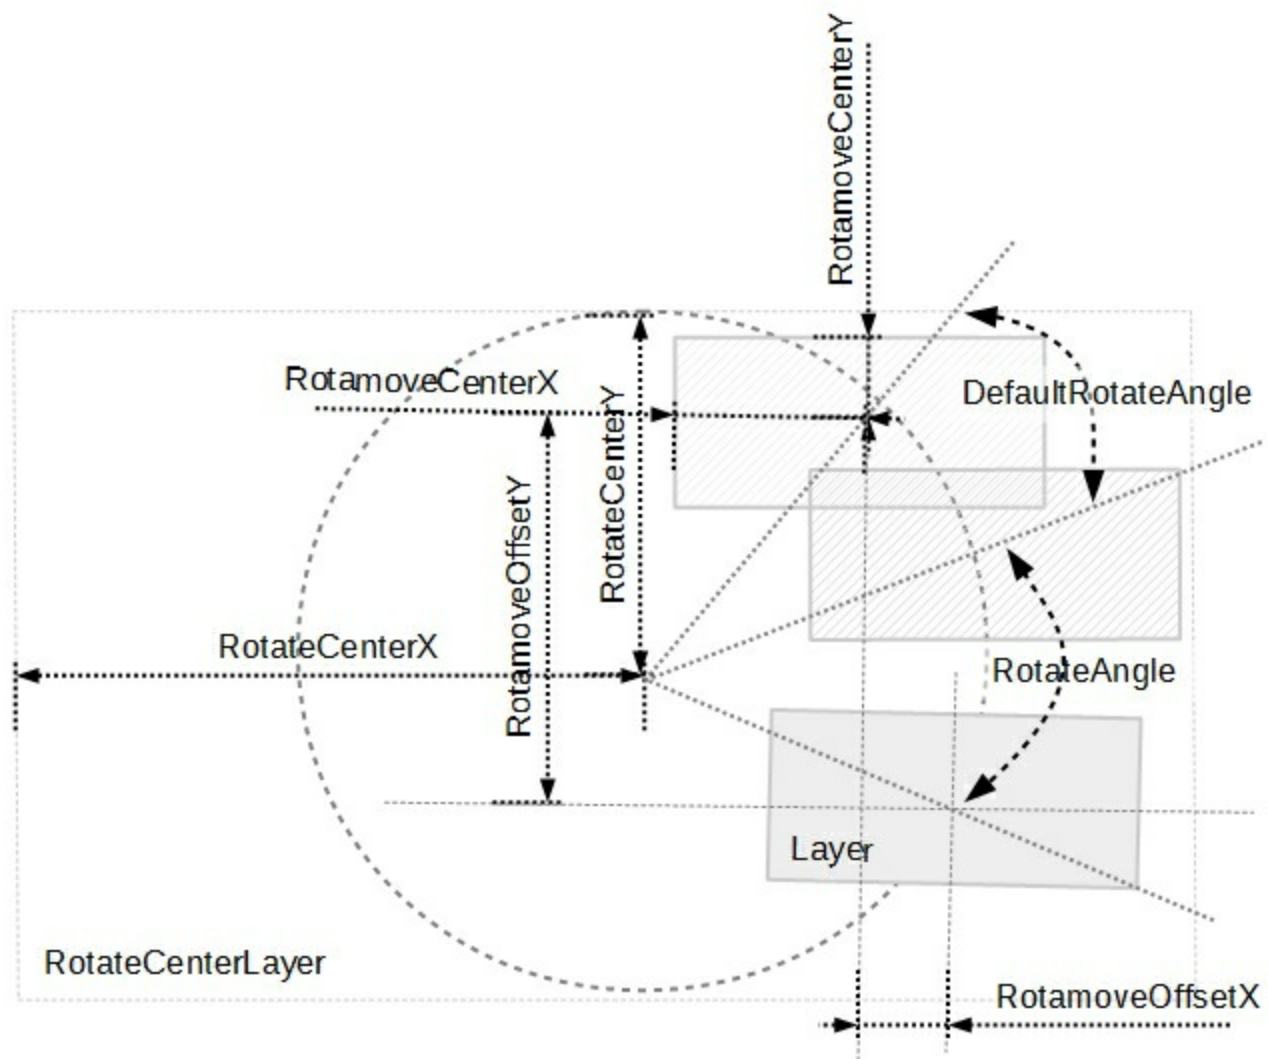

The center of the layer may be different than layer's view, as for instance, if you have a layer that's shows a knob in the bottom-side of the layer the RotamoveCenterX / RotamoveCenterY point is the center on the knob in the bottom-right side not in the center of the layer as you can see in the following screen shot (red cross) :

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is exDoRotamove:

- [RotamoveCenterX](#), specifies the x-position of the layer's center (view).
- RotamoveCenterY, specifies the y-position of the layer's center (view).
- [RotamoveOffsetX](#), specifies the x-offset of the layer.
- [RotamoveOffsetY](#), specifies the y-offset of the layer.

The following picture shows the rotamove properties of the Layer, relative to the [RotateCenterLayer](#) layer:

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the [RotateCenterLayer](#) layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the [RotateCenterLayer](#) layer.

property Layer.RotamoveOffsetX as Long

Specifies the x-offset of the layer, while the layer's drag operation is exDoRotamove.

Type	Description
Long	A Long expression that specifies the x-offset of the layer, while the layer's drag operation is exDoRotamove.

The control supports moving the layer by rotation, also called rotamove. The rotamove operation moves layer and the rotamove center pointed by [RotamoveCenterX](#) / [RotamoveCenterY](#) properties around the rotation center pointed by the [RotateCenterX](#) / [RotateCenterY](#) properties of the [RotateCenterLayer](#) layer. The following picture shows the rotamove properties of the Layer, relative to the [RotateCenterLayer](#) layer:

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is `exDoRotamove`:

- [RotamoveCenterX](#), specifies the x-position of the layer's center (view).
- [RotamoveCenterY](#), specifies the y-position of the layer's center (view).
- `RotamoveOffsetX`, specifies the x-offset of the layer.

- [RotamoveOffsetY](#), specifies the y-offset of the layer.

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the [RotateCenterLayer](#) layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the [RotateCenterLayer](#) layer.

property Layer.RotamoveOffsetY as Long

Specifies the y-offset of the layer, while the layer's drag operation is exDoRotamove.

Type	Description
Long	A Long expression that specifies the y-offset of the layer, while the layer's drag operation is exDoRotamove.

The control supports moving the layer by rotation, also called rotamove. The rotamove operation moves layer and the rotamove center pointed by [RotamoveCenterX](#) / [RotamoveCenterY](#) properties around the rotation center pointed by the [RotateCenterX](#) / [RotateCenterY](#) properties of the [RotateCenterLayer](#) layer. The following picture shows the rotamove properties of the Layer, relative to the [RotateCenterLayer](#) layer:

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is `exDoRotamove`:

- [RotamoveCenterX](#), specifies the x-position of the layer's center (view).
- [RotamoveCenterY](#), specifies the y-position of the layer's center (view).
- [RotamoveOffsetX](#), specifies the x-offset of the layer.

- [RotamoveOffsetY](#), specifies the y-offset of the layer.

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the [RotateCenterLayer](#) layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the [RotateCenterLayer](#) layer.

property Layer.RotateAngle as Double

Specifies the angle to rotate the layer.

Type	Description
Double	A Double expression that specifies the angle to rotate the layer, in degree.

By default, the RotateAngle property is 0 degree (which indicates that the layer is shown as it is). The RotateAngle property specifies the current angle of the rotation of the specified layer. The [DeltaAngle](#) property specifies the angle (in degrees) that has been rotated the layer/object, during the drag operation. The [CumulativeRotateAngle](#) property specifies the cumulative rotation angle, during the dragging operation. The [Change](#) event occurs when the layer's RotateAngle property is changed. The [DragStart](#) / [Drag](#) / [DragEnd](#) events notify your application when a layer is dragged. Change the [Debug](#) property of the [DragInfo](#) during the [DragStart](#) event to debug the rotation angles. Use the [DefaultLayer\(exDefLayerRotateAngle\)](#) property to specify the default value for the RotateAngle property, before adding any layer. The [RotateType](#) property specifies whether the layer's rotation is performed fast, by shearing (high quality rotation), ...

The following picture shows the rotation properties of the Layer, relative to the [RotateCenterLayer](#) layer:

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.

- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the [RotateCenterLayer](#) layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the [RotateCenterLayer](#) layer.

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is exDoRotamove:

- [RotamoveCenterX](#), specifies the x-position of the layer's center.
- [RotamoveCenterY](#), specifies the y-position of the layer's center.
- [RotamoveOffsetX](#), specifies the x-offset of the layer.
- [RotamoveOffsetY](#), specifies the y-offset of the layer.

property Layer.RotateAngleToValue as String

Specifies the expression to convert the rotating angle to value.

Type	Description
String	A String value that specifies the expression to convert the rotating angle to value.

By default, the RotateAngleToValue property is empty. If the RotateAngleToValue property is empty, missing or invalid, it has no effect. If the RotateAngleToValue property is valid, the result of evaluation of the RotateAngleToValue property indicates the layer's [Value](#) property. The [ValueToRotateAngle](#) property converts the value back to a rotation angle. Use the [DefaultLayer\(exDefLayerRotateAngleToValue\)](#) property to specify the default value for the RotateAngleToValue property, before adding the layer.

For instance:

- "0", specifies that the layer's value is always 0 no matter of the rotation angle of the layer.
- "value / 360 * 100", converts the angle to a percent
- "value / 360 / 24 / 60", converts the angle to a time value.

The RotateAngleToValue property supports the following keywords:

- **value** keyword indicates the layer's [RotateAngle](#) property

Also, this property supports all constants, operators and functions defined [here](#).

The [Value](#) property indicates the **value** keyword in the following properties:

- [ValueToRotateAngle](#), Specifies the expression to convert the value to rotating angle. The layer's [RotateAngle](#) property is the result of evaluating the [ValueToRotateAngle](#) expression, while the [OnDrag](#) property is exDoRotate or exDoRotamove. The RotateAngleToValue converts the current rotation angle to a value.
- [ValueToOffsetX](#), Specifies the expression to convert the value to x-offset. The layer's [OffsetX](#) property is the result of evaluating the [ValueToOffsetX](#) expression, while the [OnDrag](#) property is **exDoMove**. The OffsetToValue converts the current offset to a value.
- [ValueToOffsetY](#), Specifies the expression to convert the value to y-offset. The layer's [OffsetY](#) property is the result of evaluating the [ValueToOffsetY](#) expression, while the [OnDrag](#) property is exDoMove. The OffsetToValue converts the current offset to a value.

The following picture shows the rotation properties of the Layer, relative to the

[RotateCenterLayer](#) layer:

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the [RotateCenterLayer](#) layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the [RotateCenterLayer](#) layer.

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is `exDoRotamove`:

- [RotamoveCenterX](#), specifies the x-position of the layer's center.
- [RotamoveCenterY](#), specifies the y-position of the layer's center.
- [RotamoveOffsetX](#), specifies the x-offset of the layer.
- [RotamoveOffsetY](#), specifies the y-offset of the layer.

property Layer.RotateAngleValid as String

Validates the rotation angle of the layer.

Type	Description
String	A String expression that validates the rotation angle value of the layer. The result of evaluating the expression indicates the newly RotateAngle value.

By default, the RotateAngleValid property is empty. The RotateAngleValid property has no effect if it is empty, missing or invalid. If the RotateAngleValid property is valid expression, the value of [RotateAngle](#) property always matches RotateAngleValid expression. In other words, the RotateAngleValid validates the rotation angle of the layer. Use the [DefaultLayer\(exDefLayerRotateAngleValid\)](#) property to specify the default value for the RotateAngleValid property, before adding any layer. The [Change](#) event occurs when the layer's OffsetX property is changed. The [DragStart](#) / [Drag](#) / [DragEnd](#) events notify your application when a layer is dragged. You can debug the rotation angle, using the [Debug](#) property of the [DragInfo](#) object. During drag operation you can use the [RotateAngleValid](#) property to limit the rotation angle.

For instance:

- "0", indicates that no rotation is allowed, or in other words, [RotateAngle](#) is always 0.
- "15 * int(value / 15)", specifies that only multiply of 15 degree is allowed for [RotateAngle](#) property (sectorial rotation)
- "value = 0 ? 0 : (value < 0 ? -180 : +180)", indicates that valid values for [RotateAngle](#) property is -180, 0 and +180 (discrete rotation)
- "value MIN -90 MAX 90", indicates that values of [RotateAngle](#) property are between -90 and +90 degrees (range movement)
- "value < 90 ? value : (value < 180 ? 90 : (value < 270 ? 270 : value))", converts the value to an angle between 270 and 90 degree.
- "int(value / 360 * 100)/100 * 360" converts the value to an integer rotation angle
- "(value)/100 * 360" converts a percent value to an angle

The RotateAngleValid property supports the following keywords:

- **value** keyword indicates the current value of [RotateAngle](#) property (the value to validate)

Also, this property supports all constants, operators and functions defined [here](#).

The following picture shows the rotation properties of the Layer, relative to the [RotateCenterLayer](#) layer:

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the [RotateCenterLayer](#) layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the [RotateCenterLayer](#) layer.

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is `exDoRotamove`:

- [RotamoveCenterX](#), specifies the x-position of the layer's center.
- [RotamoveCenterY](#), specifies the y-position of the layer's center.
- [RotamoveOffsetX](#), specifies the x-offset of the layer.
- [RotamoveOffsetY](#), specifies the y-offset of the layer.

property Layer.RotateCenterLayer as Long

Indicates the index of the layer the rotation is around. If -1, the rotation is relative to the current layer.

Type	Description
Long	A Long expression that indicates the index of the layer that holds the rotation center.

By default, the RotateCenterLayer property is 0, which indicates that all layers are rotated relative to the first layer. If the RotateCenterLayer property is -1, the rotation is performed around the layer itself. Use the [DefaultLayer\(exDefLayerRotateCenterLayer\)](#) property to specify the default value for the RotateCenterLayer property, before adding the layer.

The following properties can be used to specify a different rotation center:

- RotateCenterLayer, indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the RotateCenterLayer layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the RotateCenterLayer layer.

The following picture shows the rotation properties of the Layer, relative to the [RotateCenterLayer](#) layer:

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.

- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and ValueToRotateAngle, specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is exDoRotamove:

- [RotamoveCenterX](#), specifies the x-position of the layer's center.
- [RotamoveCenterY](#), specifies the y-position of the layer's center.
- [RotamoveOffsetX](#), specifies the x-offset of the layer.
- [RotamoveOffsetY](#), specifies the y-offset of the layer.

property Layer.RotateCenterX as String

Indicates the expression that determines the x-origin of the rotation point relative to the RotateCenterLayer layer.

Type	Description
String	A String expression that determines the x-origin of the rotation point relative to the RotateCenterLayer layer.

By default, the RotateCenterX / [RotateCenterY](#) property is empty. If the RotateCenterX / [RotateCenterY](#) property is empty, missing or invalid, the center of the layer ([RotateCenterLayer](#) layer) is considered the rotation center. Use the [DefaultLayer\(exDefLayerRotateCenterX\)](#) property to specify the default value for the RotateCenterX property, before adding the layer.

You can change the [Debug](#) property (to exDebugLayerDragRotate, for instance) of the [DragInfo](#) object during the [DragStart](#) event to show the current rotation point as shown in the following screen shot:

For instance:

- "lwidth/2 + 78", defines the center 78 pixels to the right relative to the center of the layer.

The RotateCenterX property supports the following keywords:

- **lwidth** keyword, indicates the width in pixels of the layer
- **width** keyword, specifies the width in pixels of the view / control
- **lheight** keyword, indicates the height in pixels of the layer

- **height** keyword, specifies the height in pixels of the view / control

Also, this property supports all constants, operators and functions defined [here](#).

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the [RotateCenterLayer](#) layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the [RotateCenterLayer](#) layer.

The following picture shows the rotation properties of the Layer, relative to the [RotateCenterLayer](#) layer:

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is `exDoRotamove`:

- [RotamoveCenterX](#), specifies the x-position of the layer's center.
- [RotamoveCenterY](#), specifies the y-position of the layer's center.
- [RotamoveOffsetX](#), specifies the x-offset of the layer.

- [RotamoveOffsetY](#), specifies the y-offset of the layer.

property Layer.RotateCenterY as String

Indicates the expression that determines the y-origin of the rotation point relative to the RotateCenterLayer layer.

Type	Description
String	A String expression that determines the y-origin of the rotation point relative to the RotateCenterLayer layer.

By default, the [RotateCenterX](#) / RotateCenterY property is empty. If the [RotateCenterX](#) / RotateCenterY property is empty, missing or invalid, the center of the layer ([RotateCenterLayer](#) layer) is considered the rotation center. Use the [DefaultLayer\(exDefLayerRotateCenterX\)](#) property to specify the default value for the RotateCenterX property, before adding the layer.

You can change the [Debug](#) property (to exDebugLayerDragRotate, for instance) of the [DragInfo](#) object during the [DragStart](#) event to show the current rotation point as shown in the following screen shot:

For instance:

- "lwidth/2 + 78", defines the center 78 pixels to the right relative to the center of the layer.

The RotateCenterX property supports the following keywords:

- **lwidth** keyword, indicates the width in pixels of the layer
- **width** keyword, specifies the width in pixels of the view / control
- **lheight** keyword, indicates the height in pixels of the layer

- **height** keyword, specifies the height in pixels of the view / control

Also, this property supports all constants, operators and functions defined [here](#).

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the RotateCenterLayer layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the RotateCenterLayer layer.

The following picture shows the rotation properties of the Layer, relative to the [RotateCenterLayer](#) layer:

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is exDoRotamove:

- [RotamoveCenterX](#), specifies the x-position of the layer's center.
- [RotamoveCenterY](#), specifies the y-position of the layer's center.
- [RotamoveOffsetX](#), specifies the x-offset of the layer.

- [RotamoveOffsetY](#), specifies the y-offset of the layer.

property Layer.RotateClip as Boolean

Specifies whether the layer's clipping region is rotated once the layer is rotated.

Type	Description
Boolean	A Boolean expression that specifies whether the layer's clipping region is rotated once the current later is rotated.

By default, the RotateClip property is False, which indicates that has no effect. The RotateClip property specifies whether the layer's clipping region is rotated once the layer is rotated. The [Clip](#) property gets access to the layer's clipping object. Use the [DefaultLayer\(exDefLayerRotateClip\)](#) property to specify the default value for the RotateClip property, before adding the layer. The [OnDrag](#) property indicates the action to be performed when the user drags the layer. The [Selectable](#) property returns or sets a value that indicates whether the layer is selectable.

The RotateClip property has effect if:

- The RotateClip property is True.
- The current layer is rotated
- The layer's [Clip](#) property clips the current layer.

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the [RotateCenterLayer](#) layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the [RotateCenterLayer](#) layer.

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is exDoRotamove:

- [RotamoveCenterX](#), specifies the x-position of the layer's center.
- [RotamoveCenterY](#), specifies the y-position of the layer's center.
- [RotamoveOffsetX](#), specifies the x-offset of the layer.

- [RotamoveOffsetY](#), specifies the y-offset of the layer.

property Layer.RotateType as RotateTypeEnum

Returns or sets a value that indicates whether the layer's rotation is performed fast, by shearing (high quality rotation), ...

Type	Description
RotateTypeEnum	A RotateTypeEnum expression that specifies the method the rotation of the layer is performed.

By default, the RotateType property is exRotateFast. The RotateType property specifies whether the layer's rotation is performed fast, by shearing (high quality rotation), ... Use the [DefaultLayer\(exDefLayerDefaultRotateType\)](#) property to specify the default value for the RotateType property, before adding any layer.

The following screen shot shows the hands of the clock, while the RotateType property is **exRotateBilinearInterpolation**:

The following screen shot shows the hands of the clock, while the RotateType property is **exRotateFast** (by default):

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the [RotateCenterLayer](#) layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the [RotateCenterLayer](#) layer.

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is exDoRotamove:

- [RotamoveCenterX](#), specifies the x-position of the layer's center.
- [RotamoveCenterY](#), specifies the y-position of the layer's center.
- [RotamoveOffsetX](#), specifies the x-offset of the layer.
- [RotamoveOffsetY](#), specifies the y-offset of the layer.

property Layer.Selectable as Boolean

Returns or sets a value that indicates whether the layer is selectable.

Type	Description
Boolean	A Boolean expression that specifies whether the layer is selectable or unselectable.

By default, the Selectable property is True, which indicates that the layer is selectable. The Selectable property returns or sets a value that indicates whether the layer is selectable. Use the [DefaultLayer\(exDefLayerSelectable\)](#) property to specify the default value for the Selectable property, before adding any layer. The [Visible](#) property shows or hides a specific layer (visible). The [LayerFromPoint](#) property retrieves the layer from point that's visible and selectable. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (dragable). You can use the [Grayscale](#) property to show the entire layer in gray scale (disable state). For instance, you can simulate a disabled layer by changing the layer's Grayscale property on True, and setting the layer's Selectable property on False.

property Layer.ShowHandCursor as Boolean

Returns or sets a value that indicates whether the hand cursor is shown when it hovers a visible / selectable / draggable layer.

Type	Description
Boolean	A Boolean expression that indicates whether the hand cursor is shown when it hovers a visible / selectable / draggable layer.

By default, the ShowHandCursor property is True, which indicates that the hand cursor is shown over any layer that has:

- [Visible](#) property on True,
- [Selectable](#) property on True,
- [OnDrag](#) property is not exDoNothing

The [Visible](#) property shows or hides a specific layer (visible). The [Position](#) property specifies the position of the layer, in the layers collection. The [Selectable](#) property returns or sets a value that indicates whether the layer is selectable. The [LayerFromPoint](#) property retrieves the layer from point that's visible and selectable. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (draggable).

property Layer.ToolTip as String

Gets or sets a value (tooltip) that's displayed once the cursor hovers the layer.

Type	Description
String	A String expression that defines the layer's HTML tooltip that's displayed when the cursor hovers the layer.

By default, the ToolTip / ToolTipTitle property is empty, which indicates no tooltip. The ToolTip gets or sets a value (tooltip) that's displayed once the cursor hovers the layer. The ToolTipTitle property indicates the title of the layer's tooltip. The layer's tooltip is shown if any of the ToolTip / ToolTipTitle property is not empty. The ToolTipDelay property specifies the time in ms that passes before the ToolTip appears. Use the ToolTipWidth property to specify the width of the tooltip window Use the ToolTipPopDelay property specifies the period in ms of time the ToolTip remains visible if the mouse pointer is stationary within a control. Use the ToolTipFont property to change the tooltip's font. Use the Background(exToolTipAppearance) property indicates the visual appearance of the borders of the tooltips. Use the Background(exToolTipBackColor) property indicates the tooltip's background color. Use the Background(exToolTipForeColor) property indicates the tooltip's foreground color. Use the ShowToolTip method to display a custom tooltip. The DefaultLayer(exDefLayerToolTip) property specifies the default value of the ToolTip property.

The following screen shot shows the current value as a tooltip :

The ToolTip supports the following built-in HTML format:

- ** ... ** displays the text in **bold**

- `<i> ... </i>` displays the text in *italics*
- `<u> ... </u>` underlines the text
- `<s> ... </s>` Strike-through text
- `<a id;options> ... ` displays an [anchor](#) element that can be clicked. An anchor is a piece of text or some other object (for example an image) which marks the beginning and/or the end of a hypertext link. The `<a>` element is used to mark that piece of text (or inline image), and to give its hypertextual relationship to other documents. The control fires the *AnchorClick(AnchorID, Options)* event when the user clicks the anchor element. The *FormatAnchor* property customizes the visual effect for anchor elements.
- ` ... ` displays portions of text with a different font and/or different size. For instance, the "`bit`" draws the bit text using the Tahoma font, on size 12 pt. If the name of the font is missing, and instead size is present, the current font is used with a different size. For instance, "`bit`" displays the bit text using the current font, but with a different size.
- `<fgcolor rrggbb> ... </fgcolor>` or `<fgcolor=rrggb> ... </fgcolor>` displays text with a specified **foreground** color. The rr/gg/bb represents the red/green/blue values of the color in hexa values.
- `<bgcolor rrggbb> ... </bgcolor>` or `<bgcolor=rrggb> ... </bgcolor>` displays text with a specified **background** color. The rr/gg/bb represents the red/green/blue values of the color in hexa values.
- `<solidline rrggbb> ... </solidline>` or `<solidline=rrggb> ... </solidline>` draws a solid-line on the bottom side of the current text-line, of specified RGB color. The `<solidline> ... </solidline>` draws a black solid-line on the bottom side of the current text-line. The rr/gg/bb represents the red/green/blue values of the color in hexa values.
- `<dotline rrggbb> ... </dotline>` or `<dotline=rrggb> ... </dotline>` draws a dot-line on the bottom side of the current text-line, of specified RGB color. The `<dotline> ... </dotline>` draws a black dot-line on the bottom side of the current text-line. The rr/gg/bb represents the red/green/blue values of the color in hexa values.
- `<upline> ... </upline>` draws the line on the top side of the current text-line (requires `<solidline>` or `<dotline>`).
- `<r>` right aligns the text
- `<c>` centers the text
- `
` forces a line-break
- `number[:width]` inserts an icon inside the text. The number indicates the index of the icon being inserted. Use the Images method to assign a list of icons to your chart. The last 7 bits in the high significant byte of the number expression indicates the identifier of the skin being used to paint the object. Use the [Add](#) method to add new skins to the control. If you need to remove the skin appearance from a part of the control you need to reset the last 7 bits in the high significant byte of the color being applied to the part. The width is optional and indicates the width of the icon being inserted. Using the width option you can overwrite multiple icons getting a nice effect. By default, if the width field is missing, the width is 18 pixels.

- **key[:width]** inserts a custom size picture into the text being previously loaded using the HTMLPicture property. The Key parameter indicates the key of the picture being displayed. The Width parameter indicates a custom size, if you require to stretch the picture, else the original size of the picture is used.
- **&** glyph characters as **&**; (&), **<**; (<), **>**; (>), **"**; (") and **&#number;**; (the character with specified code), For instance, the **€** displays the EUR character. The **&** ampersand is only recognized as markup when it is followed by a known letter or a #character and a digit. For instance if you want to display **bold** in HTML caption you can use **>bold**;
- **<off offset> ... </off>** defines the vertical offset to display the text/element. The offset parameter defines the offset to display the element. This tag is inheritable, so the offset is keep while the associated **</off>** tag is found. You can use the **<off offset>** HTML tag in combination with the **** to define a smaller or a larger font to be displayed. For instance: "Text with **<off 6>**subscript" displays the text such as: Text with subscript The "Text with **<off -6>**superscript" displays the text such as: Text with subscript
- **<gra rrggbb;mode;blend> ... </gra>** defines a gradient text. The text color or **<fgcolor>** defines the starting gradient color, while the rr/gg/bb represents the red/green/blue values of the ending color, 808080 if missing as gray. The mode is a value between 0 and 4, 1 if missing, and blend could be 0 or 1, 0 if missing. The **** HTML tag can be used to define the height of the font. Any of the rrggbb, mode or blend field may not be specified. The **<gra>** with no fields, shows a vertical gradient color from the current text color to gray (808080). For instance the "**<gra FFFFFFFF;1;1>**gradient-center**</gra>**" generates the following picture:

gradient-center

- **<out rrggbb;width> ... </out>** shows the text with outlined characters, where rr/gg/bb represents the red/green/blue values of the outline color, 808080 if missing as gray, width indicates the size of the outline, 1 if missing. The text color or **<fgcolor>** defines the color to show the inside text. The **** HTML tag can be used to define the height of the font. For instance the "**<out 000000>**
<fgcolor=FFFFFF>outlined**</fgcolor></out>**" generates the following picture:

outlined

- **<sha rrggbb;width;offset> ... </sha>** define a text with a shadow, where rr/gg/bb represents the red/green/blue values of the shadow color, 808080 if missing as gray, width indicates the size of shadow, 4 if missing, and offset indicates the offset from the origin to display the text's shadow, 2 if missing. The text color or **<fgcolor>** defines the color to show the inside text. The **** HTML tag can be used to define the height of the font. For instance the "**<sha>**shadow**</sha>**" generates the following picture:

shadow

or "<**sha** 404040;5;0><fgcolor=FFFFFF>outline anti-aliasing</fgcolor></**sha**>" gets:

outline anti-aliasing

property Layer.ToolTipTitle as String

Gets or sets a value (title) that's displayed once the cursor hovers the layer.

Type	Description
String	A String expression that defines the title of the layer's tooltip. The title does not support HTML format.

By default, the [ToolTip](#) / ToolTipTitle property is empty, which indicates no tooltip. The ToolTipTitle property indicates the title of the layer's tooltip. The layer's tooltip is shown if any of the [ToolTip](#) / ToolTipTitle property is not empty. Use the [ToolTipWidth](#) property to specify the width of the tooltip window Use the [ToolTipPopDelay](#) property specifies the period in ms of time the ToolTip remains visible if the mouse pointer is stationary within a control. Use the [ToolTipFont](#) property to change the tooltip's font. Use the [Background\(exToolTipAppearance\)](#) property indicates the visual appearance of the borders of the tooltips. Use the [Background\(exToolTipBackColor\)](#) property indicates the tooltip's background color. Use the [Background\(exToolTipForeColor\)](#) property indicates the tooltip's foreground color. Use the [ShowToolTip](#) method to display a custom tooltip. The [DefaultLayer](#)(exDefLayerToolTipTitl) property specifies the default value of the ToolTipTitle property.

The following screen shot shows the current value as a tooltip :

property Layer.Top as String

Specifies the expression relative to the view, to determine the y-position to show the current layer on the control.

Type	Description
String	A String value that indicates the expression relative to the view, to determine the y-position to show the current layer on the control.

By default, the Top property is "0". If the Top property is empty, missing or invalid, it is considered "0". If valid, the value of evaluating the Top property indicates the top position of the layer as shown in the picture bellow. Use the [DefaultLayer\(exDefLayerTop\)](#) property to specify the default value for the Top property, before adding any layer.

For instance:

- "0" indicates the top side of the control's view
- "height / 2", half of the view or center of the control's view
- "height - 64", 64 pixels to the bottom side of the control's view

The Top property supports the following keywords:

- **width** keyword specifies the width in pixels of the control's view
- **height** keyword specifies the height in pixels of the control's view

Also, this property supports all constants, operators and functions defined [here](#).

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- Top, specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

The following picture shows the position/size properties of the Layer, relative to the view / control:

You can use the following properties to offset the view (background + foreground) inside the layer:

- [DefaultOffsetX](#), gets or sets a value that indicates the default x-offset of the layer.
- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetXValid](#), validates the x-offset value of the layer.
- [Value](#) and [ValueToOffsetX](#) specifies the expression to convert the value to x-offset.
- [DefaultOffsetY](#), gets or sets a value that indicates the default y-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.
- [OffsetYValid](#), validates the y-offset value of the layer.
- [Value](#) and [ValueToOffsetY](#) specifies the expression to convert the value to y-offset.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

property Layer.Transparency as Long

Gets or sets a value that indicates percent of the transparency to display the layer.

Type	Description
Long	A Long expression that specifies the percent of layer's transparency.

By default, the Transparency 0%, which indicates that no effect is applied to the layer. The Transparency property gets or sets a value that indicates percent of the transparency to display the layer. Use the [DefaultLayer\(exDefLayerTransparency\)](#) property to specify the default value for the Transparency property, before adding any layer.

The following screen shot shows the layer, with Transparency property on 0% (default):

The following screen shot shows the layer, with Transparency = 75:

By default, the [AllowSmoothChange](#) property is `exLayerTransparency | exLayerBrightness | exLayerContrast`. Use the `AllowSmoothChange` property to disable changing gradually any brightness / contrast or the transparency, of the layer. For instance, a gradually change means that you can change the layer's transparency from 0 to 50 in a short time, with intermediate values (smooth change).

The `AllowSmoothChange` property changes gradually one / or more properties like follow:

- [Brightness](#), Specifies the percent of brightness to apply to the layer.
- [Contrast](#), Specifies the percent of contrast to apply to the layer.
- Transparency, Gets or sets a value that indicates percent of the transparency to display the layer.

The [MouseIn](#) / [MouseOut](#) event notifies your application when the cursor is entering / leaving the layer. The [MouseMove](#) event is generated continually as the mouse pointer moves across objects. The `AllowSmoothChange` property specifies the properties of the layers that support smooth change. For instance, you can use the `MouseIn` / `MouseOut` event to change gradually the brightness / contrast or the transparency, of the layer, while the `AllowSmoothChange` property is not `exSmoothChangeless`.

property Layer.userData as Variant

Indicates any extra data associated with the layer.

Type	Description
Variant	A Variant expression that indicates any extra data associated with the layer.

By default, UserData property is empty. Use the UserData property to associate any extra data to the layer. Use the [DefaultLayer\(exDefLayerUserData\)](#) property to specify the default value for the UserData property, before adding any layer. Use the [UserData](#) of the DragInfo object to associate any extra data to the dragging operation. The [Visible](#) property shows or hides a specific layer (visible). The [Position](#) property specifies the position of the layer, in the layers collection. The [Selectable](#) property returns or sets a value that indicates whether the layer is selectable. The [LayerFromPoint](#) property retrieves the layer from point that's visible and selectable. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (draggable).

property Layer.Value as Variant

Indicates the object's value.

Type	Description
Variant	A VARIANT expression that specifies the value associated with the layer.

By default, the Value property is empty. The layer's Value could indicate its offset or its rotation angle, based on the OnDrag property. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (draggable). Use the [Value](#) property of the Clip object to associate a value with the layer's clipping region. Each layer can associate a value with it, while the control's [Value](#) property can be associated through the [LayerOfValue](#) property with the value of one of the layers within the control.

For instance:

- the control displays a clock, the value could be the current-time
- the control shows a switch, so the value could indicate the state of the switch
- the control shows a thermometer, so the value could be the current temperature
- the control displays a gauge, so the value could be the value on the gauge pointed by the needle

The [Change](#) event occurs when the layer's Value property is changed. During the Change event, you can change values of other layers as well. For instance, if the second-hand of the clock is rotated, you can rotate the hour and the minute-hands of the clock as well. The [DragStart](#) / [Drag](#) / [DragEnd](#) events notify your application when a layer is dragged. *You can call `DragInfo.Debug = -1` during the [DragStart](#) event to display debugging information like current movement, rotation angle when drag operation is performed.*

The Value property indicates the **value** keyword in the following properties:

- [ValueToOffsetX](#), Specifies the expression to convert the value to x-offset. The layer's [OffsetX](#) property is the result of evaluating the [ValueToOffsetX](#) expression, while the [OnDrag](#) property is **exDoMove**. The [OffsetToValue](#) converts the current offset to a value.
- [ValueToOffsetY](#), Specifies the expression to convert the value to y-offset. The layer's [OffsetY](#) property is the result of evaluating the [ValueToOffsetY](#) expression, while the [OnDrag](#) property is **exDoMove**. The [OffsetToValue](#) converts the current offset to a value.
- [ValueToRotateAngle](#), Specifies the expression to convert the value to rotating angle. The layer's [RotateAngle](#) property is the result of evaluating the [ValueToRotateAngle](#) expression, while the [OnDrag](#) property is **exDoRotate** or **exDoRotamove**. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The Value property works in association with the layer's [OnDrag](#) property like follows:

- If the [OnDrag](#) property is **exDoMove**, evaluating the [ValueToOffsetX](#) property indicates the layer's [OffsetX](#) property.
- If the [OnDrag](#) property is **exDoMove**, evaluating the [ValueToOffsetY](#) property indicates the layer's [OffsetY](#) property.
- If the [OnDrag](#) property is **exDoRotate** or **exDoRotamove**, evaluating the [ValueToRotateAngle](#) property indicates the layer's [RotateAngle](#) property.

For instance, having the gauge from the C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Guage folder, which includes the background and the needle pictures:

we need to define the value of the needle to be between 0 and 100, so if we call Value property on 85 we should get something like:

In conclusion, what we need to do is:

- defines the "needle" layer as rotate able, using the [OnDrag](#) property
- converts the value of 0-100, to a rotation angle, using the [ValueToRotateAngle](#) property
- converts the rotation angle from 0-360 to the value, using the [RotateAngleToValue](#) property
- limits the rotation angle, using the [RotateAngleValid](#) property

The following samples shows how you can do that:

VBA (MS Access, Excell...)

```
With Gauge1
    .BeginUpdate
    .DefaultLayer(185) = 2
    .BackColor = RGB(217,217,217)
    .PicturesPath = "C:\Program
Files\Exontrol\ExGauge\Sample\Design\Circular\Guage"
    With .Layers.Add("background")
        .Background.Picture.Name = "Guage_Background.png"
        .RotateCenterY = "Iheight/2 + 78"
    End With
    With .Layers.Add("needle")
        .Background.Picture.Name = "Guage_Needle.png"
```

```

.OnDrag = 2
.RotateAngleValid = "value < 90 ? value : (value < 180 ? 90 : ( value < 270 ? 270 :
value ))"
.RotateAngleToValue = "value >= 270 ? (value - 270)/90*50 : (value/90)*50 + 50"
.ValueToRotateAngle = "value < 50 ? (270 + value/50*90) : (value - 50)/50 * 90"
End With
.Value = 85
.EndUpdate
End With

```

VB6

```

With Gauge1
.BeginUpdate
.DefaultLayer(exDefLayerRotateType) = 2
.BackColor = RGB(217,217,217)
.PicturesPath = "C:\Program
Files\Exontrol\ExGauge\Sample\Design\Circular\Guage"
With .Layers.Add("background")
.Background.Picture.Name = "Guage_Background.png"
.RotateCenterY = "lheight/2 + 78"
End With
With .Layers.Add("needle")
.Background.Picture.Name = "Guage_Needle.png"
.OnDrag = exDoRotate
.RotateAngleValid = "value < 90 ? value : (value < 180 ? 90 : ( value < 270 ? 270 :
value ))"
.RotateAngleToValue = "value >= 270 ? (value - 270)/90*50 : (value/90)*50 + 50"
.ValueToRotateAngle = "value < 50 ? (270 + value/50*90) : (value - 50)/50 * 90"
End With
.Value = 85
.EndUpdate
End With

```

VB.NET

```

With Exgauge1
.BeginUpdate()

```

```

.set_DefaultLayer(exontrol.EXGAUGELib.DefaultLayerPropertyEnum.exDefLayerRotateTy

    .BackColor = Color.FromArgb(217,217,217)

property Layer.ValueToOffsetX as String

Specifies the expression to convert the value to x-offset.

Type	Description
String	A String value that defines the expression to convert the value to x-offset.

By default, the ValueToOffsetX property is empty. If the ValueToOffsetX property is empty, missing or invalid it has no effect. If the ValueToOffsetX property is valid, the result of evaluation of it, indicates the value of the [OffsetX](#) property, while the [OnDrag](#) property is **exDoMove**. The [OffsetXValid](#) property limits / validates the x-offset value of the layer. The [OffsetX](#) / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [Change](#) event occurs when the layer's Value property is changed. During the Change event, you can change values of other layers as well. For instance, if the second-hand of the clock is rotated, you can rotate the hour and the minute-hands of the clock as well. The [ValueToOffsetY](#) property specifies the expression to convert the value to y-offset. Use the [DefaultLayer\(exDefLayerValueToOffsetX\)](#) property to specify the default value for the ValueToOffsetX property, before adding the layer.

For instance:

- the control shows a switch, so the value could indicate the state of the switch
- the control shows a thermometer, so the value could be the current temperature

For instance:

- "0", no horizontal move, or assigns always 0 to [OffsetX](#) property
- "value / 2", specifies half of the layer's [Value](#)
- "value = 0 ? 0 : 48", indicates that the [OffsetX](#) property is 0 if the layer's [Value](#) is 0 or 48 if different than 0

The ValueToOffsetX property supports the following keywords:

- **value** keyword indicates the layer's [Value](#) property.

Also, this property supports all constants, operators and functions defined [here](#).

The [Value](#) property indicates the **value** keyword in the following properties:

- ValueToOffsetX, Specifies the expression to convert the value to x-offset. The layer's [OffsetX](#) property is the result of evaluating the ValueToOffsetX expression, while the [OnDrag](#) property is **exDoMove**. The [OffsetToValue](#) converts the current offset to a value.

- [ValueToOffsetY](#), Specifies the expression to convert the value to y-offset. The layer's [OffsetY](#) property is the result of evaluating the [ValueToOffsetY](#) expression, while the [OnDrag](#) property is exDoMove. The [OffsetToValue](#) converts the current offset to a value.
- [ValueToRotateAngle](#), Specifies the expression to convert the value to rotating angle. The layer's [RotateAngle](#) property is the result of evaluating the [ValueToRotateAngle](#) expression, while the [OnDrag](#) property is exDoRotate or exDoRotamove. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The Value property works in association with the layer's [OnDrag](#) property like follows:

- If the [OnDrag](#) property is **exDoMove**, evaluating the ValueToOffsetX property indicates the layer's [OffsetX](#) property.
- If the [OnDrag](#) property is exDoMove, evaluating the [ValueToOffsetY](#) property indicates the layer's [OffsetY](#) property.
- If the [OnDrag](#) property is exDoRotate or exDoRotamove, evaluating the [ValueToRotateAngle](#) property indicates the layer's [RotateAngle](#) property.

property Layer.ValueToOffsetY as String

Specifies the expression to convert the value to y-offset.

Type	Description
String	A String value that defines the expression to convert the value to y-offset.

By default, the ValueToOffsetY property is empty. If the ValueToOffsetY property is empty, missing or invalid it has no effect. If the ValueToOffsetY property is valid, the result of evaluation of it, indicates the value of the [OffsetY](#) property, while the [OnDrag](#) property is **exDoMove**. The [OffsetYValid](#) property limits / validates the y-offset value of the layer. The [OffsetX](#) / [OffsetY](#) property specifies the (x,y)-position of the layer, relative to the upper-left corner of the control. The [Change](#) event occurs when the layer's Value property is changed. During the Change event, you can change values of other layers as well. For instance, if the second-hand of the clock is rotated, you can rotate the hour and the minute-hands of the clock as well. The [ValueToOffsetX](#) property specifies the expression to convert the value to x-offset. Use the [DefaultLayer\(exDefLayerValueToOffsetY\)](#) property to specify the default value for the ValueToOffsetY property, before adding the layer.

For instance:

- the control shows a switch, so the value could indicate the state of the switch
- the control shows a thermometer, so the value could be the current temperature

For instance:

- "0", no vertical move, or assigns always 0 to [OffsetY](#) property
- "value / 2", specifies half of the layer's [Value](#)
- "value = 0 ? 0 : 48", indicates that the [OffsetY](#) property is 0 if the layer's [Value](#) is 0 or 48 if different than 0

The ValueToOffsetY property supports the following keywords:

- **value** keyword indicates the layer's [Value](#) property.

Also, this property supports all constants, operators and functions defined [here](#).

The [Value](#) property indicates the **value** keyword in the following properties:

- [ValueToOffsetX](#), Specifies the expression to convert the value to x-offset. The layer's [OffsetX](#) property is the result of evaluating the [ValueToOffsetX](#) expression, while the [OnDrag](#) property is **exDoMove**. The [OffsetToValue](#) converts the current offset to a value.
- ValueToOffsetY, Specifies the expression to convert the value to y-offset. The layer's

[OffsetY](#) property is the result of evaluating the ValueToOffsetY expression, while the [OnDrag](#) property is **exDoMove**. The [OffsetToValue](#) converts the current offset to a value.

- [ValueToRotateAngle](#), Specifies the expression to convert the value to rotating angle. The layer's [RotateAngle](#) property is the result of evaluating the [ValueToRotateAngle](#) expression, while the [OnDrag](#) property is exDoRotate or exDoRotamove. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The Value property works in association with the layer's [OnDrag](#) property like follows:

- If the [OnDrag](#) property is exDoMove, evaluating the [ValueToOffsetX](#) property indicates the layer's [OffsetX](#) property.
- If the [OnDrag](#) property is **exDoMove**, evaluating the ValueToOffsetY property indicates the layer's [OffsetY](#) property.
- If the [OnDrag](#) property is exDoRotate or exDoRotamove, evaluating the [ValueToRotateAngle](#) property indicates the layer's [RotateAngle](#) property.

property Layer.ValueToRotateAngle as String

Specifies the expression to convert the value to rotating angle

Type	Description
String	A String value that defines the expression to convert the value to rotating angle

By default, the ValueToRotateAngle property is empty. If the ValueToRotateAngle property is empty, missing or invalid it has no effect. If the ValueToRotateAngle property is valid, the result of evaluation of it, indicates the value of the [RotateAngle](#) property, while the [OnDrag](#) property is **exDoRotate** or **exDoRotamove**. The [RotateAngleValid](#) property limits / validates the rotation angle of the layer. The [RotateAngle](#) property specifies the angle to rotate the layer. The [Change](#) event occurs when the layer's Value property is changed. During the Change event, you can change values of other layers as well. For instance, if the second-hand of the clock is rotated, you can rotate the hour and the minute-hands of the clock as well. Use the [DefaultLayer\(exDefLayerValueToRotateAngle\)](#) property to specify the default value for the ValueToRotateAngle property, before adding the layer. The [RotateAngleToValue](#) converts the current rotation angle to a value.

For instance:

- the control displays a clock, the value could be the current-time
- the control displays a gauge, so the value could be the value on the gauge pointed by the needle

For instance:

- "0", no rotation, or assigns always 0 to [RotateAngle](#) property
- "value / 2", specifies half of the layer's [Value](#)
- "value / 100 * 360", [Value](#) percent from 360 degree. For instance, if the value is 50, the expression returns 180, and if 100, the expression returns 360
- "value < 50 ? (270 + value/50*90) : (value - 50)/50 * 90", for a value less than 50 returns the angle between 270 and 360, and for a value grater than 50, from 0 to 90
- "2 * 360 * ((0:=(value < 0 ? floor(value) + 1 - value : value - floor(value))) < 0.5 ? =:0 : (0:= (=:0 - 0.5)))", indicates the position (rotation angle) of the clock's hours-hand giving the time value.
- "((1:=((0:=(value < 0 ? floor(value) + 1 - value : value - floor(value))) < 0.5 ? =:0 : (0:= (=:0 - 0.5))) * 24)) - floor(=:1)) * 360", indicates the position (rotation angle) of the clock's minutes-hand giving the time value.
- "((2:=(((1:=((0:=(value < 0 ? floor(value) + 1 - value : value - floor(value))) < 0.5 ? =:0 : (0:= (=:0 - 0.5))) * 24)) - floor(=:1)) * 60)) - floor(=:2)) * 360", indicates the position (rotation angle) of the clock's seconds-hand giving the time value.

The `ValueToRotateAngle` property supports the following keywords:

- **value** keyword indicates the layer's [Value](#) property.

Also, this property supports all constants, operators and functions defined [here](#).

The [Value](#) property indicates the **value** keyword in the following properties:

- `ValueToRotateAngle`, Specifies the expression to convert the value to rotating angle. The layer's [RotateAngle](#) property is the result of evaluating the [ValueToRotateAngle](#) expression, while the [OnDrag](#) property is `exDoRotate` or `exDoRotamove`. The [RotateAngleToValue](#) converts the current rotation angle to a value.
- [ValueToOffsetX](#), Specifies the expression to convert the value to x-offset. The layer's [OffsetX](#) property is the result of evaluating the `ValueToOffsetX` expression, while the [OnDrag](#) property is **exDoMove**. The [OffsetToValue](#) converts the current offset to a value.
- [ValueToOffsetY](#), Specifies the expression to convert the value to y-offset. The layer's [OffsetY](#) property is the result of evaluating the [ValueToOffsetY](#) expression, while the [OnDrag](#) property is `exDoMove`. The [OffsetToValue](#) converts the current offset to a value.

The following picture shows the rotation properties of the Layer, relative to the [RotateCenterLayer](#) layer:

Any of the following properties can be used to rotate the layer:

- [DefaultRotateAngle](#), specifies the default angle to rotate the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.

- [RotateAngleValid](#), validates / limits the rotation angle of the layer.
- [Value](#) and [ValueToRotateAngle](#), specifies the expression to convert the value to rotating angle. The [RotateAngleToValue](#) converts the current rotation angle to a value.

The following properties can be used to specify a different rotation center:

- [RotateCenterLayer](#), indicates the index of the layer the rotation is around.
- [RotateCenterX](#), indicates the expression that determines the x-origin of the rotation point relative to the [RotateCenterLayer](#) layer.
- [RotateCenterY](#), indicates the expression that determines the y-origin of the rotation point relative to the [RotateCenterLayer](#) layer.

The following properties can be used to change the rotation center, while the layer's [OnDrag](#) property is `exDoRotamove`:

- [RotamoveCenterX](#), specifies the x-position of the layer's center.
- [RotamoveCenterY](#), specifies the y-position of the layer's center.
- [RotamoveOffsetX](#), specifies the x-offset of the layer.
- [RotamoveOffsetY](#), specifies the y-offset of the layer.

property Layer.Visible as Boolean

Retrieves or sets a value indicating whether the layer is visible or hidden.

Type	Description
Boolean	A Boolean expression that specifies whether the layer is visible or hidden.

By default, the Visible property is True, so the layer is visible. The Visible property shows or hides a specific layer (visible). Use the [DefaultLayer\(exDefLayerVisible\)](#) property to specify the default value for the Visible property, before adding any layer. The [Position](#) property specifies the position of the layer, in the layers collection. The [Selectable](#) property returns or sets a value that indicates whether the layer is selectable. The [LayerFromPoint](#) property retrieves the layer from point that's visible and selectable. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (dragable). The [ShowLayers](#) property indicates the only layers to be shown on the control.

The following properties can be used to access Layer objects in the control:

- [Item](#) property, gives the Layer object based on its index / key. The [Count](#) property specifies the number of layers within the control
- [VisibleItem](#) property, gives the visible layer based on its position. The VisibleCount property indicates the number of visible layers within the control. The [ShowLayers](#) property indicates the only layers to be shown on the control.

property Layer.Width as String

Specifies the expression relative to the view, to determine the width to show the current layer on the control.

Type	Description
String	A String value that specifies the expression relative to the view, to determine the width to show the current layer on the control.

By default, the Width property is "width". If the Width property is empty, missing or invalid, it is considered "width". If valid, the value of evaluating the Width property indicates the width of the layer as shown in the picture bellow. Use the [DefaultLayer\(exDefLayerWidth\)](#) property to specify the default value for the Width property, before adding any layer. The [LayerAutoSize](#) property resizes all layers based on the picture of the first layer.

For instance:

- "0" indicates that the layer's width is 0
- "width / 2", half of the view or center of the control's view
- "width - 64", 64 pixels to the right side of the control's view

The Width property supports the following keywords:

- **width** keyword specifies the width in pixels of the control's view
- **height** keyword specifies the height in pixels of the control's view

Also, this property supports all constants, operators and functions defined [here](#).

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- Width, specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

The following picture shows the position/size properties of the Layer, relative to the view / control:

You can use the following properties to offset the view (background + foreground) inside the layer:

- [DefaultOffsetX](#), gets or sets a value that indicates the default x-offset of the layer.
- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetXValid](#), validates the x-offset value of the layer.
- [Value](#) and [ValueToOffsetX](#) specifies the expression to convert the value to x-offset.
- [DefaultOffsetY](#), gets or sets a value that indicates the default y-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.
- [OffsetYValid](#), validates the y-offset value of the layer.
- [Value](#) and [ValueToOffsetY](#) specifies the expression to convert the value to y-offset.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

Layers object

The Layers object holds a collection of [Layer](#) objects. The [Layers](#) property gives access to the control's Layers collection. Any layer can display unlimited opaque / transparent graphics, HTML text, can be visible, selectable, draggable and so on. Any layer can change its position in the layers collection as well. The Layer can change its brightness, contrast, grayscale or transparency as well.

The following screen show shows a control with 10 layers:

while the following screen shot shows how the layers are arranged:

The Layers collection supports the following properties and methods.

Name	Description
Add	Adds a Layer object to the collection and returns a reference to the newly created object.
Clear	Removes all objects in a collection.
Count	Specifies the number of layers.
Item	Returns a specific Layer of the Layers collection.
Remove	Removes a specific member from the Layers collection.
VisibleCount	Specifies the number of visible layers.
VisibleItem	Returns the visible Layer of the Layers collection, based on its position.

Method Layers.Add ([Key as Variant])

Adds a Layer object to the collection and returns a reference to the newly created object.

Type	Description
Key as Variant	[Optional] A VARIANT expression that indicates the key to identify the newly create layer.
Return	Description
Layer	A Layer object that indicates the newly created layer.

The Add method adds a new layer to the control. The [Count](#) property specifies the number of layers in the control. The [PicturesPath](#) Specifies the path to load the pictures from. The [PicturesName](#) property specifies the expression that indicates the name of the picture to be loaded on each layer. The [Item](#) property of the Layers collection accesses a Layer giving its index or key. The [Index](#) property is read-only and zero-based, which indicates that the layer with the Index property 0, it is the first layer, while the layer with the index Count - 1, is the last layer in the control (in z-order). The [Background](#) object holds pictures to be shown on the layer's background. The [Foreground](#) property of the Layer access the layer's Foreground object. The **for each** statement can be used to enumerate Layer objects in the Layers collection. The [ShowLayers](#) property indicates the only layers to be shown on the control.

The following properties can be used to add / remove layers within the control:

- Count property, adds / removes layers to / from the control
- [Add](#) method, adds a new layer to the control.

The following properties can be used to access Layer objects in the control:

- [Item](#) property, gives the Layer object based on its index / key. The [Count](#) property specifies the number of layers within the control
- [VisibleItem](#) property, gives the visible layer based on its position. The [VisibleCount](#) property indicates the number of visible layers within the control. The [Visible](#) property shows or hides the layer. The [ShowLayers](#) property indicates the only layers to be shown on the control.

The following sample creates a view from two pictures: "[Guage_Background.png](#)" and "[Guage_Needle.png](#)" from the C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Guage.

The sample shows how to add two new layers with the keys: **"background"** and **"needle"**

VBA (MS Access, Excell...)

```
With Gauge1
    .BeginUpdate
    .PicturesPath = "C:\Program
Files\Exontrol\ExGauge\Sample\Design\Circular\Guage"
    .Layers.Add("background").Background.Picture.Name = "Guage_Background.png"
    .Layers.Add("needle").Background.Picture.Name = "Guage_Needle.png"
    .EndUpdate
End With
```

With Gauge1

.BeginUpdate

.PicturesPath = "C:\Program

Files\Exontrol\ExGauge\Sample\Design\Circular\Guage"

.Layers.Add("background").Background.Picture.Name = "Guage_Background.png"

.Layers.Add("needle").Background.Picture.Name = "Guage_Needle.png"

.EndUpdate

End With

VB.NET

RETURN

method **Layers.Clear ()**

Removes all objects in a collection.

Type	Description
------	-------------

The Clear removes all layers from the control. The [Count](#) property specifies the number of layers in the control. The [PicturesPath](#) Specifies the path to load the pictures from. The [PicturesName](#) property specifies the expression that indicates the name of the picture to be loaded on each layer. The [Item](#) property of the Layers collection accesses a Layer giving its index or key. The [Index](#) property is read-only and zero-based, which indicates that the layer with the Index property 0, it is the first layer, while the layer with the index Count - 1, is the last layer in the control (in z-order). The [Background](#) object holds pictures to be shown on the layer's background. The [Foreground](#) property of the Layer access the layer's Foreground object. The **for each** statement can be used to enumerate Layer objects in the Layers collection.

The following properties can be used to remove layers within the control:

- [Count](#) property, adds / removes layers to / from the control. For instance, Count property on 0, removes all layers from the control.
- Clear removes all layers from the control.
- [Remove](#) method, removes a layer from the control based on its index or key.

The following properties can be used to access Layer objects in the control:

- [Item](#) property, gives the Layer object based on its index / key. The [Count](#) property specifies the number of layers within the control
- [VisibleItem](#) property, gives the visible layer based on its position. The [VisibleCount](#) property indicates the number of visible layers within the control. The [Visible](#) property shows or hides the layer. The [ShowLayers](#) property indicates the only layers to be shown on the control.

property Layers.Count as Long

Specifies the number of layers.

Type	Description
Long	A Long expression that specifies the count of layers within the control.

The Count property specifies the number of layers in the control. The [PicturesPath](#) Specifies the path to load the pictures from. The [PicturesName](#) property specifies the expression that indicates the name of the picture to be loaded on each layer. The [Item](#) property of the Layers collection accesses a Layer giving its index or key. The [Index](#) property is read-only and zero-based, which indicates that the layer with the Index property 0, it is the first layer, while the layer with the index Count - 1, is the last layer in the control (in z-order). The [Background](#) object holds pictures to be shown on the layer's background. The [Foreground](#) property of the Layer access the layer's Foreground object. The **for each** statement can be used to enumerate Layer objects in the Layers collection.

The following properties can be used to add / remove layers within the control:

- Count property, adds / removes layers to / from the control
- [Add](#) method, adds a new layer to the control.

The following properties can be used to access Layer objects in the control:

- [Item](#) property, gives the Layer object based on its index / key. The Count property specifies the number of layers within the control
- [VisibleItem](#) property, gives the visible layer based on its position. The [VisibleCount](#) property indicates the number of visible layers within the control. The [Visible](#) property shows or hides the layer. The [ShowLayers](#) property indicates the only layers to be shown on the control.

The following samples use the Layers.Count property to add new layers:

VBA (MS Access, Excell...)

```
With Gauge1
    .BeginUpdate
    .PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob

RETURN

property Layers.Item (Key as Variant) as Layer

Returns a specific Layer of the Layers collection.

Type	Description
Key as Variant	A long expression that indicates the index of the layer to be requested, or any other value that indicates the key of the layer.
Layer	A Layer object being requested.

The Item property of the Layers collection accesses a Layer giving its index or key. The [Index](#) property is read-only and zero-based, which indicates that the layer with the Index property 0, it is the first layer, while the layer with the index [Count](#) - 1, is the last layer in the control (in z-order). The [Background](#) object holds pictures to be shown on the layer's background. The [Foreground](#) property of the Layer access the layer's Foreground object. The **for each** statement can be used to enumerate Layer objects in the Layers clection.

The following properties can be used to access Layer objects in the control:

- Item property, gives the Layer object based on its index / key. The [Count](#) property specifies the number of layers within the control
- [VisibleItem](#) property, gives the visible layer based on its position. The [VisibleCount](#) property indicates the number of visible layers within the control. The [Visible](#) property shows or hides the layer. The [ShowLayers](#) property indicates the only layers to be shown on the control.

The following properties can be used to add layers within the control:

- [Count](#) property, adds layers to the control
- [Add](#) method, adds a new layer to the control.

The following properties can be used to remove layers within the control:

- [Count](#) property, removes layers from the control. For instance, Count property on 0, removes all layers from the control.
- [Clear](#) removes all layers from the control.
- [Remove](#) method, removes a layer from the control based on its index or key.

method Layers.Remove (Key as Variant)

Removes a specific member from the Layers collection.

Type	Description
Key as Variant	A Long expression that specifies the index of the layer to be removed, or any other value to specify the key of the layer to be removed.

The Remove method removes a layer from the control based on its index or key. The [Clear](#) removes all layers from the control. The [Count](#) property specifies the number of layers in the control. The [PicturesPath](#) Specifies the path to load the pictures from. The [PicturesName](#) property specifies the expression that indicates the name of the picture to be loaded on each layer. The [Item](#) property of the Layers collection accesses a Layer giving its index or key. The [Index](#) property is read-only and zero-based, which indicates that the layer with the Index property 0, it is the first layer, while the layer with the index Count - 1, is the last layer in the control (in z-order). The [Background](#) object holds pictures to be shown on the layer's background. The [Foreground](#) property of the Layer access the layer's Foreground object. The **for each** statement can be used to enumerate Layer objects in the Layers collection.

The following properties can be used to remove layers within the control:

- [Count](#) property, adds / removes layers to / from the control. For instance, Count property on 0, removes all layers from the control.
- Clear removes all layers from the control.
- [Remove](#) method, removes a layer from the control based on its index or key.

The following properties can be used to access Layer objects in the control:

- [Item](#) property, gives the Layer object based on its index / key. The [Count](#) property specifies the number of layers within the control
- [VisibleItem](#) property, gives the visible layer based on its position. The [VisibleCount](#) property indicates the number of visible layers within the control. The [Visible](#) property shows or hides the layer. The [ShowLayers](#) property indicates the only layers to be shown on the control.

property Layers.VisibleCount as Long

Specifies the number of visible layers.

Type	Description
Long	A Long expression that specifies the number of visible layers.

The VisibleCount property indicates the number of visible layers within the control. The [VisibleItem](#) property gives the visible layer based on its position. The [Visible](#) property shows or hides the layer. The [ShowLayers](#) property indicates the only layers to be shown on the control. The [Item](#) property of the Layers collection accesses a Layer giving its index or key. The [Index](#) property is read-only and zero-based, which indicates that the layer with the Index property 0, it is the first layer, while the layer with the index [Count](#) - 1, is the last layer in the control (in z-order). The [Background](#) object holds pictures to be shown on the layer's background. The [Foreground](#) property of the Layer access the layer's Foreground object. The **for each** statement can be used to enumerate Layer objects in the Layers clection.

The following properties can be used to access Layer objects in the control:

- [Item](#) property, gives the Layer object based on its index / key. The [Count](#) property specifies the number of layers within the control
- [VisibleItem](#) property, gives the visible layer based on its position. The VisibleCount property indicates the number of visible layers within the control. The [Visible](#) property shows or hides the layer. The [ShowLayers](#) property indicates the only layers to be shown on the control.

The following properties can be used to add layers within the control:

- [Count](#) property, adds layers to the control
- [Add](#) method, adds a new layer to the control.

The following properties can be used to remove layers within the control:

- [Count](#) property, removes layers from the control. For instance, Count property on 0, removes all layers from the control.
- [Clear](#) removes all layers from the control.
- [Remove](#) method, removes a layer from the control based on its index or key.

property Layers.VisibleItem (Position as Long) as Layer

Returns the visible Layer of the Layers collection, based on its position.

Type	Description
Position as Long	A long expression that specifies the position of the visible layer. The value should be between 0 and VisibleCount - 1
Layer	A Layer object that specifies the visible layer object

The VisibleItem property gives the visible layer based on its position. The [VisibleCount](#) property indicates the number of visible layers within the control. The [Visible](#) property shows or hides the layer. The [ShowLayers](#) property indicates the only layers to be shown on the control. The [Item](#) property of the Layers collection accesses a Layer giving its index or key. The [Index](#) property is read-only and zero-based, which indicates that the layer with the Index property 0, it is the first layer, while the layer with the index [Count](#) - 1, is the last layer in the control (in z-order). The [Background](#) object holds pictures to be shown on the layer's background. The [Foreground](#) property of the Layer access the layer's Foreground object. The **for each** statement can be used to enumerate Layer objects in the Layers clection.

The following properties can be used to access Layer objects in the control:

- [Item](#) property, gives the Layer object based on its index / key. The [Count](#) property specifies the number of layers within the control
- VisibleItem property, gives the visible layer based on its position. The [VisibleCount](#) property indicates the number of visible layers within the control. The [Visible](#) property shows or hides the layer. The [ShowLayers](#) property indicates the only layers to be shown on the control.

The following properties can be used to add layers within the control:

- [Count](#) property, adds layers to the control
- [Add](#) method, adds a new layer to the control.

The following properties can be used to remove layers within the control:

- [Count](#) property, removes layers from the control. For instance, Count property on 0, removes all layers from the control.
- [Clear](#) removes all layers from the control.
- [Remove](#) method, removes a layer from the control based on its index or key.

LColor object

The LColor object holds information about a solid / EBN color to be shown on the layer's background. The [Picture](#) / [ExtraPicture](#) property should be used to place a picture on the layer's background.

The following screen shot shows a layer with solid red color:

The LColor object supports the following properties and methods:

Name	Description
Selectable	Returns or sets a value that indicates whether the color is selectable.
Value	Indicates the solid color/visual appearance to be shown on the layer's background.
Visible	Specifies if the color is visible or hidden.

property LColor.Selectable as Boolean

Returns or sets a value that indicates whether the color is selectable.

Type	Description
Boolean	A Boolean expression that specifies whether the color on the layer's background is selectable.

By default, the Selectable property is True, so the user can select the layer if the cursor hovers the solid color. The Selectable property specifies whether the color on the layer's background is selectable. You can use the [Grayscale](#) property to show the entire layer in gray scale (disable state). Use the [Value](#) property to specify a solid / EBN color to be applied on the layer's background. For instance, you can use Selectable property on False, to prevent selecting the layer when the user selects the portion of the layer that displays the solid color. The [Selectable](#) property of the Background object, affects all the pictures / colors being shown on the layer's background.

The solid / EBN color is applied on the layer's background if both of the following:

- Visible property is True
- [Value](#) property is different than -1 value

are accomplished.

property LColor.Value as Color

Indicates the solid color/visual appearance to be shown on the layer's background.

Type	Description
Color	A Color expression that specifies the solid / EBN color to be shown on the layer's background. The last 7 bits in the high significant byte of the color indicates the identifier of the skin being used. Use the Add method to add new skins to the control. If you need to remove the skin appearance from a part of the control you need to reset the last 7 bits in the high significant byte of the color being applied to the background's part.

By default, Value property is -1, which indicates that the layer's background is transparent (no effect). Use the Value property to specify a solid / EBN color to be applied on the layer's background. The [Visible](#) property specifies whether the color is applied on the layer's background. The [Picture](#) / [ExtraPicture](#) property should be used to place a picture on the layer's background.

The solid / EBN color is applied on the layer's background if both of the following:

- [Visible](#) property is True
- Value property is different than -1 value

are accomplished.

The following properties can be used to move / resize the layer:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.

The following screen shot shows a layer with solid red color:

And if we decompose the layers we get:

The following samples show how you can apply a solid color to be display on left-half of the layer after the first visible layer:

VBA (MS Access, Excell...)

```
With Gauge1
    .BeginUpdate
    .PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob
1"
    .PicturesName = "`Layer` + int(value + 1) + `.png`"
    .Layers.Count = 5
    With .Layers.Add("Solid")
        .Position = 1
        .Width = "width/2"

RETURN

property LColor.Visible as Boolean

Specifies if the color is visible or hidden.

Type	Description
Boolean	A Boolean expression that specifies whether the color is applied on the layer's background.

By default, the Visible property is True, so the color is applied on the layer's background. Use the [Value](#) property to specify a solid / EBN color to be applied on the layer's background. For instance, you can use Visible property on False, to prevent showing the solid color on the layer's background. The [Selectable](#) property specifies whether the color on the layer's background is selectable. The [Visible](#) property of the Background object, affects all the pictures / colors being shown on the layer's background.

The solid / EBN color is applied on the layer's background if both of the following:

- Visible property is True
- [Value](#) property is different than -1 value

are accomplished.

LPicture object

The LPicture object holds a picture to be displayed on the layer's background. The Layer's background can display unlimited graphics of different sizes and positions. The [Picture](#) / [ExtraPicture](#) property adds a picture on the layer's background.

For instance, having the following files in the folder C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Clock,

By loading each picture on a layer, we get something like:

The LPicture object supports the following properties and methods:

Name	Description
DisplayAs	Retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
Height	Specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.
Left	Specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
Name	Indicates the picture to be shown on the layer's background.

[Opaque](#)

Indicates if the picture is opaque or transparent.

[Selectable](#)

Returns or sets a value that indicates whether the picture is selectable.

[Top](#)

Specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.

[TransparentColorFrom](#)

Specifies the transparent color to define transparency part of the current picture (to).

[TransparentColorTo](#)

Specifies the transparent color to define transparency part of the current picture (to).

[Value](#)

Indicates the picture to be shown on the layer's background.

[Visible](#)

Specifies if the picture is shown or hidden on the layer's background.

[Width](#)

Specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.

property LPicture.DisplayAs as PictureDisplayEnum

Retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.

Type	Description
PictureDisplayEnum	A PictureDisplayEnum expression that indicates the way how the graphic is displayed on the layer's background.

By default, the DisplayAs property is Stretch, that specifies that the picture is stretched on the layer's background. Use the DisplayAs property to specify a different the way how the graphic is displayed on the layer's background.

The following properties determines the position / size of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

property LPicture.Height as String

Specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

Type	Description
String	A String value that defines the expression relative to the view/current picture, to determine the height to show the current picture on the background.

By default, the Height property is "**height**", which specifies the height in pixels of the layer where the picture is displayed. You can use the Height property of the LPicture object to show the picture with a different height. The [LayerAutoSize](#) property resizes all layers based on the picture of the first layer.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- Height, specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.

- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.

For instance, the following sample shows the picture on a size of 64,64 in the center of the layer:

```
With .Background.Picture
.Width = "64"
.Height = "64"
.Left = "(width - 64)/2"
.Top = "(height - 64)/2"
End With
```

The Height property supports the following keywords:

- **pwidth**, specifies the width in pixels of the picture object
- **pheight**, specifies the height in pixels of the picture object
- **width**, specifies the width in pixels of the layer where the picture is displayed.
- **height**, specifies the height in pixels of the layer where the picture is displayed.

The Height property supports the following constants, operators and functions:

The constants are (DPI-Aware components):

- **dpi** (DPI constant), specifies the current DPI setting. and it indicates the minimum value between **dpix** and **dpiy** constants. For instance, if current DPI setting is 100%, the dpi constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpi returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%
- **dpix** (DPIX constant), specifies the current DPI setting on x-scale. For instance, if current DPI setting is 100%, the dpix constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpix returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%
- **dpiy** (DPIY constant), specifies the current DPI setting on y-scale. For instance, if current DPI setting is 100%, the dpiy constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpiy returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%

The supported binary arithmetic operators are:

- ***** (multiplicity operator), priority 5
- **/** (divide operator), priority 5
- **mod** (reminder operator), priority 5
- **+** (addition operator), priority 4 (concatenates two strings, if one of the operands is

of string type)

- - (subtraction operator), priority 4

The supported unary boolean operators are:

- **not** (not operator), priority 3 (high priority)

The supported binary boolean operators are:

- **or** (or operator), priority 2
- **and** (and operator), priority 1

The supported binary boolean operators, all these with the same priority 0, are :

- < (less operator)
- <= (less or equal operator)
- = (equal operator)
- != (not equal operator)
- >= (greater or equal operator)
- > (greater operator)

The supported binary range operators, all these with the same priority 5, are :

- **MIN** (min operator), indicates the minimum value, so a **MIN** b returns the value of a, if it is less than b, else it returns b. For instance, the expression value MIN 10 returns always a value greater than 10.
- **MAX** (max operator), indicates the maximum value, so a **MAX** b returns the value of a, if it is greater than b, else it returns b. For instance, the expression value MAX 100 returns always a value less than 100.

The supported binary operators, all these with the same priority 0, are :

- **:= (Store operator)**, stores the result of expression to variable. The syntax for := operator is

variable := expression

where variable is a integer between 0 and 9. You can use the **:=** operator to restore any stored variable (please make the difference between **:=** and **=**). For instance, **(0:=dbl(value)) = 0 ? "zero" : :=0**, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the **:=** and **=** are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

- **=: (Restore operator)**, restores the giving variable (previously saved using the store operator). The syntax for =: operator is

=: variable

where variable is a integer between 0 and 9. You can use the := operator to store the value of any expression (please make the difference between := and =:). For instance, $(0:=dbl(value)) = 0 ? "zero" : =:0$, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the := and =: are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

The supported ternary operators, all these with the same priority 0, are :

- **? (Immediate If operator)**, returns and executes one of two expressions, depending on the evaluation of an expression. The syntax for ? operator is

expression ? true_part : false_part

, while it executes and returns the true_part if the expression is true, else it executes and returns the false_part. For instance, the $\%0 = 1 ? 'One' : (\%0 = 2 ? 'Two' : 'not found')$ returns 'One' if the value is 1, 'Two' if the value is 2, and 'not found' for any other value. A n-ary equivalent operation is the case() statement, which is available in newer versions of the component.

The supported n-ary operators are (with priority 5):

- **array (at operator)**, returns the element from an array giving its index (0 base). The array operator returns empty if the element is found, else the associated element in the collection if it is found. The syntax for array operator is

expression array (c1,c2,c3,...cn)

, where the c1, c2, ... are constant elements. The constant elements could be numeric, date or string expressions. For instance the *month(value)-1 array* ('J','F','M','A','M','Jun','J','A','S','O','N','D') is equivalent with *month(value)-1 case* (default:"; 0:'J';1:'F';2:'M';3:'A';4:'M';5:'Jun';6:'J';7:'A';8:'S';9:'O';10:'N';11:'D').

- **in (include operator)**, specifies whether an element is found in a set of constant elements. The in operator returns -1 (True) if the element is found, else 0 (false) is retrieved. The syntax for in operator is

expression in (c1,c2,c3,...cn)

, where the c_1, c_2, \dots are constant elements. The constant elements could be numeric, date or string expressions. For instance the *value in (11,22,33,44,13)* is equivalent with *(expression = 11) or (expression = 22) or (expression = 33) or (expression = 44) or (expression = 13)*. The *in* operator is not a time consuming as the equivalent *or* version is, so when you have large number of constant elements it is recommended using the *in* operator. Shortly, if the collection of elements has 1000 elements the *in* operator could take up to 8 operations in order to find if an element fits the set, else if the *or* statement is used, it could take up to 1000 operations to check, so by far, the *in* operator could save time on finding elements within a collection.

- **switch** (*switch operator*), returns the value being found in the collection, or a predefined value if the element is not found (default). The syntax for *switch* operator is

expression switch (default,c1,c2,c3,...,cn)

, where the c_1, c_2, \dots are constant elements, and the default is a constant element being returned when the element is not found in the collection. The constant elements could be numeric, date or string expressions. The equivalent syntax is " $\%0 = c_1 ? c_1 : (\%0 = c_2 ? c_2 : (\dots ? \dots : default))$ ". The *switch* operator is very similar with the *in* operator excepts that the first element in the switch is always returned by the statement if the element is not found, while the returned value is the value itself instead -1. For instance, the $\%0 \text{ switch } ('not\ found', 1, 4, 7, 9, 11)$ gets 1, 4, 7, 9 or 11, or 'not found' for any other value. As the *in* operator the *switch* operator uses binary searches for fitting the element, so it is quicker than *iif* (immediate if operator) alternative.

- **case()** (*case operator*) returns and executes one of n expressions, depending on the evaluation of the expression (*IIF* - immediate IF operator is a binary *case()* operator). The syntax for *case()* operator is:

expression case ([default : default_expression ;] c1 : expression1 ; c2 : expression2 ; c3 : expression3 ;....)

If the default part is missing, the *case()* operator returns the value of the expression if it is not found in the collection of cases (c_1, c_2, \dots). For instance, if the value of expression is not any of c_1, c_2, \dots the *default_expression* is executed and returned. If the value of the expression is c_1 , then the *case()* operator executes and returns the *expression1*. The *default, c1, c2, c3, ...* must be constant elements as numbers, dates or strings. For instance, the *date(shortdate(value)) case (default:0 ; #1/1/2002#:1 ; #2/1/2002#:1; #4/1/2002#:1; #5/1/2002#:1)* indicates that only #1/1/2002#, #2/1/2002#, #4/1/2002# and #5/1/2002# dates returns 1, since the others returns 0. For instance the following sample specifies the hour being non-working for specified dates: *date(shortdate(value)) case(default:0;#4/1/2009# : hour(value) >= 6 and hour(value) <= 12 ; #4/5/2009# : hour(value) >= 7 and hour(value) <= 10 or*

hour(value) in(15,16,18,22); #5/1/2009# : hour(value) <= 8) statement indicates the working hours for dates as follows:

- *#4/1/2009#*, from hours 06:00 AM to 12:00 PM
- *#4/5/2009#*, from hours 07:00 AM to 10:00 AM and hours 03:00PM, 04:00PM, 06:00PM and 10:00PM
- *#5/1/2009#*, from hours 12:00 AM to 08:00 AM

The *in*, *switch* and *case()* use binary search to look for elements so they are faster than using *if* and *or* expressions. Obviously, the priority of the operations inside the expression is determined by () parenthesis and the priority for each operator.

The supported conversion unary operators are:

- **type** (unary operator) retrieves the type of the object. For instance *type(%1) = 8* specifies the cells (on the column 1) that contains string values.

Here's few predefined types:

- 0 - empty (not initialized)
- 1 - null
- 2 - short
- 3 - long
- 4 - float
- 5 - double
- 6 - currency
- 7 - date
- 8 - string
- 9 - object
- 10 - error
- 11 - boolean
- 12 - variant
- 13 - any
- 14 - decimal
- 16 - char
- 17 - byte
- 18 - unsigned short
- 19 - unsigned long
- 20 - long on 64 bits
- 21 - unsigned long on 64 bites
- **str** (unary operator) converts the expression to a string. The *str* operator converts the expression to a string. For instance, the *str(-12.54)* returns the string "-12.54".
- **dbl** (unary operator) converts the expression to a number. The *dbl* operator converts the expression to a number. For instance, the *dbl("12.54")* returns 12.54

- **date** (unary operator) converts the expression to a date, based on your regional settings. For instance, the *date``* gets the current date (no time included), the *date`now`* gets the current date-time, while the *date("01/01/2001")* returns #1/1/2001#
- **dateS** (unary operator) converts the string expression to a date using the format MM/DD/YYYY HH:MM:SS. For instance, the *dateS("01/01/2001 14:00:00")* returns #1/1/2001 14:00:00#

Other known operators for numbers are:

- **int** (unary operator) retrieves the integer part of the number. For instance, the *int(12.54)* returns 12
- **round** (unary operator) rounds the number ie 1.2 gets 1, since 1.8 gets 2. For instance, the *round(12.54)* returns 13
- **floor** (unary operator) returns the largest number with no fraction part that is not greater than the value of its argument. For instance, the *floor(12.54)* returns 12
- **abs** (unary operator) retrieves the absolute part of the number ie -1 gets 1, 2 gets 2. For instance, the *abs(-12.54)* returns 12.54
- **sin** (unary operator) returns the sine of an angle of x radians. For instance, the *sin(3.14)* returns 0.001593.
- **cos** (unary operator) returns the cosine of an angle of x radians. For instance, the *cos(3.14)* returns -0.999999.
- **asin** (unary operator) returns the principal value of the arc sine of x, expressed in radians. For instance, the *2*asin(1)* returns the value of PI.
- **acos** (unary operator) returns the principal value of the arc cosine of x, expressed in radians. For instance, the *2*acos(0)* returns the value of PI
- **sqrt** (unary operator) returns the square root of x. For instance, the *sqrt(81)* returns 9.
- **currency** (unary operator) formats the giving number as a currency string, as indicated by the control panel. For instance, *currency(value)* displays the value using the current format for the currency ie, 1000 gets displayed as \$1,000.00, for US format.
- value **format** 'flags' (binary operator) formats the value with specified flags. If flags is empty, the number is displayed as shown in the field "Number" in the "Regional and Language Options" from the Control Panel. For instance the *1000 format "* displays 1,000.00 for English format, while 1.000,00 is displayed for German format. *1000 format '2|.|3|,'* will always displays 1,000.00 no matter of settings in the control panel. If formatting the number fails for some invalid parameter, the value is displayed with no formatting.

The ' flags' for format operator is a list of values separated by | character such as 'NumDigits|DecimalSep|Grouping|ThousandSep|NegativeOrder|LeadingZero' with the following meanings:

- *NumDigits* - specifies the number of fractional digits, If the flag is missing, the field "No. of digits after decimal" from "Regional and Language Options" is using.
- *DecimalSep* - specifies the decimal separator. If the flag is missing, the field "Decimal symbol" from "Regional and Language Options" is using.
- *Grouping* - indicates the number of digits in each group of numbers to the left of the decimal separator. Values in the range 0 through 9 and 32 are valid. The most significant grouping digit indicates the number of digits in the least significant group immediately to the left of the decimal separator. Each subsequent grouping digit indicates the next significant group of digits to the left of the previous group. If the last value supplied is not 0, the remaining groups repeat the last group. Typical examples of settings for this member are: 0 to group digits as in 123456789.00; 3 to group digits as in 123,456,789.00; and 32 to group digits as in 12,34,56,789.00. If the flag is missing, the field "Digit grouping" from "Regional and Language Options" indicates the grouping flag.
- *ThousandSep* - specifies the thousand separator. If the flag is missing, the field "Digit grouping symbol" from "Regional and Language Options" is using.
- *NegativeOrder* - indicates the negative number mode. If the flag is missing, the field "Negative number format" from "Regional and Language Options" is using. The valid values are 0, 1, 2, 3 and 4 with the following meanings:
 - 0 - Left parenthesis, number, right parenthesis; for example, (1.1)
 - 1 - Negative sign, number; for example, -1.1
 - 2 - Negative sign, space, number; for example, - 1.1
 - 3 - Number, negative sign; for example, 1.1-
 - 4 - Number, space, negative sign; for example, 1.1 -
- *LeadingZero* - indicates if leading zeros should be used in decimal fields. If the flag is missing, the field "Display leading zeros" from "Regional and Language Options" is using. The valid values are 0, 1

Other known operators for strings are:

- **len** (unary operator) retrieves the number of characters in the string. For instance, the *len("Mihai")* returns 5.
- **lower** (unary operator) returns a string expression in lowercase letters. For instance, the *lower("MIHAI")* returns "mihai"
- **upper** (unary operator) returns a string expression in uppercase letters. For instance, the *upper("mihai")* returns "MIHAI"
- **proper** (unary operator) returns from a character expression a string capitalized as appropriate for proper names. For instance, the *proper("mihai")* returns "Mihai"
- **ltrim** (unary operator) removes spaces on the left side of a string. For instance, the *ltrim(" mihai")* returns "mihai"
- **rtrim** (unary operator) removes spaces on the right side of a string. For instance, the *rtrim("mihai ")* returns "mihai"
- **trim** (unary operator) removes spaces on both sides of a string. For instance, the

trim(" mihai ") returns "mihai"

- **reverse** (unary operator) reverses the order of the characters in the string a. For instance, the *reverse("Mihai")* returns "iahIM"
- **startswith** (binary operator) specifies whether a string starts with specified string (0 if not found, -1 if found). For instance *"Mihai" startwith "Mi"* returns -1
- **endwith** (binary operator) specifies whether a string ends with specified string (0 if not found, -1 if found). For instance *"Mihai" endwith "ai"* returns -1
- **contains** (binary operator) specifies whether a string contains another specified string (0 if not found, -1 if found). For instance *"Mihai" contains "ha"* returns -1
- **left** (binary operator) retrieves the left part of the string. For instance *"Mihai" left 2* returns "Mi".
- **right** (binary operator) retrieves the right part of the string. For instance *"Mihai" right 2* returns "ai"
- a **lfind** b (binary operator) The a lfind b (binary operator) searches the first occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" lfind "C"* returns 2
- a **rfind** b (binary operator) The a rfind b (binary operator) searches the last occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" rfind "C"* returns 5.
- a **mid** b (binary operator) retrieves the middle part of the string a starting from b (1 means first position, and so on). For instance *"Mihai" mid 2* returns "ihai"
- a **count** b (binary operator) retrieves the number of occurrences of the b in a. For instance *"Mihai" count "i"* returns 2.
- a **replace b with c** (double binary operator) replaces in a the b with c, and gets the result. For instance, the *"Mihai" replace "i" with ""* returns "Mha" string, as it replaces all "i" with nothing.
- a **split** b, splits the a using the separator b, and returns an array. For instance, the *weekday(value) array 'Sun Mon Thu Wed Thu Fri Sat' split ' '* gets the weekday as string. This operator can be used with the array.

Other known operators for dates are:

- **time** (unary operator) retrieves the time of the date in string format, as specified in the control's panel. For instance, the *time(#1/1/2001 13:00#)* returns "1:00:00 PM"
- **timeF** (unary operator) retrieves the time of the date in string format, as "HH:MM:SS". For instance, the *timeF(#1/1/2001 13:00#)* returns "13:00:00"
- **shortdate** (unary operator) formats a date as a date string using the short date format, as specified in the control's panel. For instance, the *shortdate(#1/1/2001 13:00#)* returns "1/1/2001"
- **shortdateF** (unary operator) formats a date as a date string using the "MM/DD/YYYY" format. For instance, the *shortdateF(#1/1/2001 13:00#)* returns "01/01/2001"

- **dateF** (unary operator) converts the date expression to a string expression in "MM/DD/YYYY HH:MM:SS" format. For instance, the *dateF(#01/01/2001 14:00:00#)* returns #01/01/2001 14:00:00#
- **longdate** (unary operator) formats a date as a date string using the long date format, as specified in the control's panel. For instance, the *longdate(#1/1/2001 13:00#)* returns "Monday, January 01, 2001"
- **year** (unary operator) retrieves the year of the date (100,...,9999). For instance, the *year(#12/31/1971 13:14:15#)* returns 1971
- **month** (unary operator) retrieves the month of the date (1, 2,...,12). For instance, the *month(#12/31/1971 13:14:15#)* returns 12.
- **day** (unary operator) retrieves the day of the date (1, 2,...,31). For instance, the *day(#12/31/1971 13:14:15#)* returns 31
- **yearday** (unary operator) retrieves the number of the day in the year, or the days since January 1st (0, 1,...,365). For instance, the *yearday(#12/31/1971 13:14:15#)* returns 365
- **weekday** (unary operator) retrieves the number of days since Sunday (0 - Sunday, 1 - Monday,..., 6 - Saturday). For instance, the *weekday(#12/31/1971 13:14:15#)* returns 5.
- **hour** (unary operator) retrieves the hour of the date (0, 1, ..., 23). For instance, the *hour(#12/31/1971 13:14:15#)* returns 13
- **min** (unary operator) retrieves the minute of the date (0, 1, ..., 59). For instance, the *min(#12/31/1971 13:14:15#)* returns 14
- **sec** (unary operator) retrieves the second of the date (0, 1, ..., 59). For instance, the *sec(#12/31/1971 13:14:15#)* returns 15

The Exontrol's [eXPression](#) component is a syntax-editor that helps you to define, view, edit and evaluate expressions. Using the eXPression component you can easily view or check if the expression you have used is syntactically correct, and you can evaluate what is the result you get giving different values to be tested. The Exontrol's eXPression component can be used as an user-editor, to configure your applications.

property LPicture.Left as String

Specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.

Type	Description
String	A String value that defines the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.

By default, the Left property is "0". You can use the Left property of the LPicture object to show the picture moved to the left or to the right.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- Left, specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.

For instance, the following sample shows the picture on a size of 64,64 in the center of the layer:

```
With .Background.Picture
.Width = "64"
.Height = "64"
.Left = "(width - 64)/2"
.Top = "(height - 64)/2"
End With
```

The Left property supports the following keywords:

- **pwidth**, specifies the width in pixels of the picture object
- **pheight**, specifies the height in pixels of the picture object
- **width**, specifies the width in pixels of the layer where the picture is displayed.
- **height**, specifies the height in pixels of the layer where the picture is displayed.

The Left property supports the following constants, operators and functions:

The constants are (DPI-Aware components):

- **dpi** (DPI constant), specifies the current DPI setting. and it indicates the minimum value between **dpix** and **dpiy** constants. For instance, if current DPI setting is 100%, the dpi constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpi returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%
- **dpix** (DPIX constant), specifies the current DPI setting on x-scale. For instance, if current DPI setting is 100%, the dpix constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpix returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%
- **dpiy** (DPIY constant), specifies the current DPI setting on y-scale. For instance, if current DPI setting is 100%, the dpiy constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpiy returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%

The supported binary arithmetic operators are:

- ***** (multiplicity operator), priority 5
- **/** (divide operator), priority 5
- **mod** (reminder operator), priority 5
- **+** (addition operator), priority 4 (concatenates two strings, if one of the operands is of string type)
- **-** (subtraction operator), priority 4

The supported unary boolean operators are:

- **not** (not operator), priority 3 (high priority)

The supported binary boolean operators are:

- **or** (or operator), priority 2
- **and** (or operator), priority 1

The supported binary boolean operators, all these with the same priority 0, are :

- **<** (less operator)
- **<=** (less or equal operator)
- **=** (equal operator)
- **!=** (not equal operator)
- **>=** (greater or equal operator)
- **>** (greater operator)

The supported binary range operators, all these with the same priority 5, are :

- **MIN** (min operator), indicates the minimum value, so a **MIN** b returns the value of a, if it is less than b, else it returns b. For instance, the expression value MIN 10 returns always a value greater than 10.
- **MAX** (max operator), indicates the maximum value, so a **MAX** b returns the value of a, if it is greater than b, else it returns b. For instance, the expression value MAX 100 returns always a value less than 100.

The supported binary operators, all these with the same priority 0, are :

- **:= (Store operator)**, stores the result of expression to variable. The syntax for := operator is

variable := expression

where variable is a integer between 0 and 9. You can use the **:=** operator to restore any stored variable (please make the difference between **:=** and **=:**). For instance, **(0:=dbl(value)) = 0 ? "zero" : =:0**, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the **:=** and **=:** are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

- **=: (Restore operator)**, restores the giving variable (previously saved using the store operator). The syntax for **=:** operator is

:= variable

where variable is a integer between 0 and 9. You can use the ***:=*** operator to store the value of any expression (please make the difference between ***:=*** and ***=***). For instance, ***(0:=dbl(value)) = 0 ? "zero" : :=0***, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the ***:=*** and ***=*** are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

The supported ternary operators, all these with the same priority 0, are :

- ***? (Immediate If operator)***, returns and executes one of two expressions, depending on the evaluation of an expression. The syntax for ***?*** operator is

expression ? true_part : false_part

, while it executes and returns the ***true_part*** if the expression is true, else it executes and returns the ***false_part***. For instance, the ***%0 = 1 ? 'One' : (%0 = 2 ? 'Two' : 'not found')*** returns 'One' if the value is 1, 'Two' if the value is 2, and 'not found' for any other value. A n-ary equivalent operation is the ***case()*** statement, which is available in newer versions of the component.

The supported n-ary operators are (with priority 5):

- ***array (at operator)***, returns the element from an array giving its index (0 base). The ***array*** operator returns empty if the element is found, else the associated element in the collection if it is found. The syntax for ***array*** operator is

expression array (c1,c2,c3,...cn)

, where the ***c1***, ***c2***, ... are constant elements. The constant elements could be numeric, date or string expressions. For instance the ***month(value)-1 array ('J','F','M','A','M','Jun','J','A','S','O','N','D')*** is equivalent with ***month(value)-1 case (default:"; 0:'J';1:'F';2:'M';3:'A';4:'M';5:'Jun';6:'J';7:'A';8:'S';9:'O';10:'N';11:'D')***.

- ***in (include operator)***, specifies whether an element is found in a set of constant elements. The ***in*** operator returns -1 (True) if the element is found, else 0 (false) is retrieved. The syntax for ***in*** operator is

expression in (c1,c2,c3,...cn)

, where the ***c1***, ***c2***, ... are constant elements. The constant elements could be numeric, date or string expressions. For instance the ***value in (11,22,33,44,13)*** is equivalent with ***(expression = 11) or (expression = 22) or (expression = 33) or (expression = 44) or***

(*expression* = 13). The *in* operator is not a time consuming as the equivalent *or* version is, so when you have large number of constant elements it is recommended using the *in* operator. Shortly, if the collection of elements has 1000 elements the *in* operator could take up to 8 operations in order to find if an element fits the set, else if the *or* statement is used, it could take up to 1000 operations to check, so by far, the *in* operator could save time on finding elements within a collection.

- ***switch*** (*switch operator*), returns the value being found in the collection, or a predefined value if the element is not found (default). The syntax for *switch* operator is

expression switch (default,c1,c2,c3,...,cn)

, where the *c1*, *c2*, ... are constant elements, and the *default* is a constant element being returned when the element is not found in the collection. The constant elements could be numeric, date or string expressions. The equivalent syntax is "*%0 = c 1 ? c 1 : (%0 = c 2 ? c 2 : (... ? . : default))*". The *switch* operator is very similar with the *in* operator excepts that the first element in the switch is always returned by the statement if the element is not found, while the returned value is the value itself instead -1. For instance, the *%0 switch ('not found',1,4,7,9,11)* gets 1, 4, 7, 9 or 11, or 'not found' for any other value. As the *in* operator the *switch* operator uses binary searches for fitting the element, so it is quicker than *iif* (immediate if operator) alternative.

- ***case()*** (*case operator*) returns and executes one of *n* expressions, depending on the evaluation of the expression (*IIF* - immediate IF operator is a binary *case()* operator). The syntax for *case()* operator is:

expression case ([default : default_expression ;] c1 : expression1 ; c2 : expression2 ; c3 : expression3 ;....)

If the default part is missing, the *case()* operator returns the value of the expression if it is not found in the collection of cases (*c1*, *c2*, ...). For instance, if the value of expression is not any of *c1*, *c2*, the *default_expression* is executed and returned. If the value of the expression is *c1*, then the *case()* operator executes and returns the *expression1*. The *default*, *c1*, *c2*, *c3*, ... must be constant elements as numbers, dates or strings. For instance, the *date(shortdate(value)) case (default:0 ; #1/1/2002#:1 ; #2/1/2002#:1; #4/1/2002#:1; #5/1/2002#:1)* indicates that only #1/1/2002#, #2/1/2002#, #4/1/2002# and #5/1/2002# dates returns 1, since the others returns 0. For instance the following sample specifies the hour being non-working for specified dates: *date(shortdate(value)) case(default:0;#4/1/2009# : hour(value) >= 6 and hour(value) <= 12 ; #4/5/2009# : hour(value) >= 7 and hour(value) <= 10 or hour(value) in(15,16,18,22); #5/1/2009# : hour(value) <= 8)* statement indicates the working hours for dates as follows:

- #4/1/2009#, from hours 06:00 AM to 12:00 PM
- #4/5/2009#, from hours 07:00 AM to 10:00 AM and hours 03:00PM, 04:00PM, 06:00PM and 10:00PM
- #5/1/2009#, from hours 12:00 AM to 08:00 AM

The *in*, *switch* and *case()* use binary search to look for elements so they are faster than using *if* and *or* expressions. Obviously, the priority of the operations inside the expression is determined by () parenthesis and the priority for each operator.

The supported conversion unary operators are:

- **type** (unary operator) retrieves the type of the object. For instance *type(%1) = 8* specifies the cells (on the column 1) that contains string values.

Here's few predefined types:

- 0 - empty (not initialized)
- 1 - null
- 2 - short
- 3 - long
- 4 - float
- 5 - double
- 6 - currency
- 7 - date
- 8 - string
- 9 - object
- 10 - error
- 11 - boolean
- 12 - variant
- 13 - any
- 14 - decimal
- 16 - char
- 17 - byte
- 18 - unsigned short
- 19 - unsigned long
- 20 - long on 64 bits
- 21 - unsigned long on 64 bites
- **str** (unary operator) converts the expression to a string. The *str* operator converts the expression to a string. For instance, the *str(-12.54)* returns the string "-12.54".
- **dbl** (unary operator) converts the expression to a number. The *dbl* operator converts the expression to a number. For instance, the *dbl("12.54")* returns 12.54
- **date** (unary operator) converts the expression to a date, based on your regional settings. For instance, the *date(`)* gets the current date (no time included), the

date(now) gets the current date-time, while the *date("01/01/2001")* returns #1/1/2001#

- **dateS** (unary operator) converts the string expression to a date using the format MM/DD/YYYY HH:MM:SS. For instance, the *dateS("01/01/2001 14:00:00")* returns #1/1/2001 14:00:00#

Other known operators for numbers are:

- **int** (unary operator) retrieves the integer part of the number. For instance, the *int(12.54)* returns 12
- **round** (unary operator) rounds the number ie 1.2 gets 1, since 1.8 gets 2. For instance, the *round(12.54)* returns 13
- **floor** (unary operator) returns the largest number with no fraction part that is not greater than the value of its argument. For instance, the *floor(12.54)* returns 12
- **abs** (unary operator) retrieves the absolute part of the number ie -1 gets 1, 2 gets 2. For instance, the *abs(-12.54)* returns 12.54
- **sin** (unary operator) returns the sine of an angle of x radians. For instance, the *sin(3.14)* returns 0.001593.
- **cos** (unary operator) returns the cosine of an angle of x radians. For instance, the *cos(3.14)* returns -0.999999.
- **asin** (unary operator) returns the principal value of the arc sine of x, expressed in radians. For instance, the *2*asin(1)* returns the value of PI.
- **acos** (unary operator) returns the principal value of the arc cosine of x, expressed in radians. For instance, the *2*acos(0)* returns the value of PI
- **sqrt** (unary operator) returns the square root of x. For instance, the *sqrt(81)* returns 9.
- **currency** (unary operator) formats the giving number as a currency string, as indicated by the control panel. For instance, *currency(value)* displays the value using the current format for the currency ie, 1000 gets displayed as \$1,000.00, for US format.
- value **format** 'flags' (binary operator) formats the value with specified flags. If flags is empty, the number is displayed as shown in the field "Number" in the "Regional and Language Options" from the Control Panel. For instance the *1000 format "* displays 1,000.00 for English format, while 1.000,00 is displayed for German format. *1000 format '2|.|3|,'* will always displays 1,000.00 no matter of settings in the control panel. If formatting the number fails for some invalid parameter, the value is displayed with no formatting.

The ' flags' for format operator is a list of values separated by | character such as 'NumDigits|DecimalSep|Grouping|ThousandSep|NegativeOrder|LeadingZero' with the following meanings:

- *NumDigits* - specifies the number of fractional digits, If the flag is missing, the field "No. of digits after decimal" from "Regional and Language Options" is using.
- *DecimalSep* - specifies the decimal separator. If the flag is missing, the field

"Decimal symbol" from "Regional and Language Options" is using.

- **Grouping** - indicates the number of digits in each group of numbers to the left of the decimal separator. Values in the range 0 through 9 and 32 are valid. The most significant grouping digit indicates the number of digits in the least significant group immediately to the left of the decimal separator. Each subsequent grouping digit indicates the next significant group of digits to the left of the previous group. If the last value supplied is not 0, the remaining groups repeat the last group. Typical examples of settings for this member are: 0 to group digits as in 123456789.00; 3 to group digits as in 123,456,789.00; and 32 to group digits as in 12,34,56,789.00. If the flag is missing, the field "Digit grouping" from "Regional and Language Options" indicates the grouping flag.
- **ThousandSep** - specifies the thousand separator. If the flag is missing, the field "Digit grouping symbol" from "Regional and Language Options" is using.
- **NegativeOrder** - indicates the negative number mode. If the flag is missing, the field "Negative number format" from "Regional and Language Options" is using. The valid values are 0, 1, 2, 3 and 4 with the following meanings:
 - 0 - Left parenthesis, number, right parenthesis; for example, (1.1)
 - 1 - Negative sign, number; for example, -1.1
 - 2 - Negative sign, space, number; for example, - 1.1
 - 3 - Number, negative sign; for example, 1.1-
 - 4 - Number, space, negative sign; for example, 1.1 -
- **LeadingZero** - indicates if leading zeros should be used in decimal fields. If the flag is missing, the field "Display leading zeros" from "Regional and Language Options" is using. The valid values are 0, 1

Other known operators for strings are:

- **len** (unary operator) retrieves the number of characters in the string. For instance, the *len("Mihai")* returns 5.
- **lower** (unary operator) returns a string expression in lowercase letters. For instance, the *lower("MIHAI")* returns "mihai"
- **upper** (unary operator) returns a string expression in uppercase letters. For instance, the *upper("mihai")* returns "MIHAI"
- **proper** (unary operator) returns from a character expression a string capitalized as appropriate for proper names. For instance, the *proper("mihai")* returns "Mihai"
- **ltrim** (unary operator) removes spaces on the left side of a string. For instance, the *ltrim(" mihai")* returns "mihai"
- **rtrim** (unary operator) removes spaces on the right side of a string. For instance, the *rtrim("mihai ")* returns "mihai"
- **trim** (unary operator) removes spaces on both sides of a string. For instance, the *trim(" mihai ")* returns "mihai"
- **reverse** (unary operator) reverses the order of the characters in the string a. For instance, the *reverse("Mihai")* returns "iahIM"

- **startswith** (binary operator) specifies whether a string starts with specified string (0 if not found, -1 if found). For instance *"Mihai" startswith "Mi"* returns -1
- **endwith** (binary operator) specifies whether a string ends with specified string (0 if not found, -1 if found). For instance *"Mihai" endwith "ai"* returns -1
- **contains** (binary operator) specifies whether a string contains another specified string (0 if not found, -1 if found). For instance *"Mihai" contains "ha"* returns -1
- **left** (binary operator) retrieves the left part of the string. For instance *"Mihai" left 2* returns "Mi".
- **right** (binary operator) retrieves the right part of the string. For instance *"Mihai" right 2* returns "ai"
- a **lfind** b (binary operator) The a lfind b (binary operator) searches the first occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" lfind "C"* returns 2
- a **rfind** b (binary operator) The a rfind b (binary operator) searches the last occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" rfind "C"* returns 5.
- a **mid** b (binary operator) retrieves the middle part of the string a starting from b (1 means first position, and so on). For instance *"Mihai" mid 2* returns "ihai"
- a **count** b (binary operator) retrieves the number of occurrences of the b in a. For instance *"Mihai" count "i"* returns 2.
- a **replace** b with c (double binary operator) replaces in a the b with c, and gets the result. For instance, the *"Mihai" replace "i" with ""* returns "Mha" string, as it replaces all "i" with nothing.
- a **split** b, splits the a using the separator b, and returns an array. For instance, the *weekday(value) array 'Sun Mon Thu Wed Thu Fri Sat' split ' '* gets the weekday as string. This operator can be used with the array.

Other known operators for dates are:

- **time** (unary operator) retrieves the time of the date in string format, as specified in the control's panel. For instance, the *time(#1/1/2001 13:00#)* returns "1:00:00 PM"
- **timeF** (unary operator) retrieves the time of the date in string format, as "HH:MM:SS". For instance, the *timeF(#1/1/2001 13:00#)* returns "13:00:00"
- **shortdate** (unary operator) formats a date as a date string using the short date format, as specified in the control's panel. For instance, the *shortdate(#1/1/2001 13:00#)* returns "1/1/2001"
- **shortdateF** (unary operator) formats a date as a date string using the "MM/DD/YYYY" format. For instance, the *shortdateF(#1/1/2001 13:00#)* returns "01/01/2001"
- **dateF** (unary operator) converts the date expression to a string expression in "MM/DD/YYYY HH:MM:SS" format. For instance, the *dateF(#01/01/2001 14:00:00#)* returns #01/01/2001 14:00:00#

- **longdate** (unary operator) formats a date as a date string using the long date format, as specified in the control's panel. For instance, the *longdate(#1/1/2001 13:00#)* returns "Monday, January 01, 2001"
- **year** (unary operator) retrieves the year of the date (100,...,9999). For instance, the *year(#12/31/1971 13:14:15#)* returns 1971
- **month** (unary operator) retrieves the month of the date (1, 2,...,12). For instance, the *month(#12/31/1971 13:14:15#)* returns 12.
- **day** (unary operator) retrieves the day of the date (1, 2,...,31). For instance, the *day(#12/31/1971 13:14:15#)* returns 31
- **yearday** (unary operator) retrieves the number of the day in the year, or the days since January 1st (0, 1,...,365). For instance, the *yearday(#12/31/1971 13:14:15#)* returns 365
- **weekday** (unary operator) retrieves the number of days since Sunday (0 - Sunday, 1 - Monday,..., 6 - Saturday). For instance, the *weekday(#12/31/1971 13:14:15#)* returns 5.
- **hour** (unary operator) retrieves the hour of the date (0, 1, ..., 23). For instance, the *hour(#12/31/1971 13:14:15#)* returns 13
- **min** (unary operator) retrieves the minute of the date (0, 1, ..., 59). For instance, the *min(#12/31/1971 13:14:15#)* returns 14
- **sec** (unary operator) retrieves the second of the date (0, 1, ..., 59). For instance, the *sec(#12/31/1971 13:14:15#)* returns 15

The Exontrol's [eXPression](#) component is a syntax-editor that helps you to define, view, edit and evaluate expressions. Using the eXPression component you can easily view or check if the expression you have used is syntactically correct, and you can evaluate what is the result you get giving different values to be tested. The Exontrol's eXPression component can be used as an user-editor, to configure your applications.

property LPicture.Name as Variant

Indicates the picture to be shown on the layer's background.

Type	Description
Variant	<p>The Name property could be one of the following:</p> <ul style="list-style-type: none">• A String expression indicates:<ul style="list-style-type: none">◦ a name of a picture file in the PicturePath folder. For instance, Name = "Layer1.png", loads the Layer1.png file if found in the PicturePath folder.◦ a picture file including its absolute path. For instance, Name = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\K loads the Layer1.png file from absolute path◦ a key of the HTML picture, previously loaded by the HTMLPicture method. For instance, Name = "pic1", loads the HTML picture with the key pic1, so the pic1 should be load previously with a HTMLPicture call like HTMLPicture("pic1") = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\K◦ an encode BASE64 string of a picture file. The Exontrol's ExImages Tool encode/decode BASE64 strings from/to pictures. In this case, the string starts with "gB..", "gC.." and so on.• A Picture object that indicates the picture to be displayed. For instance, Name = LoadPicture("picture.jpg")

By default, the Name / [Value](#) property is initialized by evaluating the control's [PicturesName](#) property, whose **value** keyword is replaced by the [Index](#) of the current layer. The Name / [Value](#) property are equivalents, so use any of them do the same.

The control supports almost all type of pictures like

- **PNG** (Portable Network Graphics) is a raster graphics file format that supports lossless data compression. PNG was created as an improved, non-patented replacement for Graphics Interchange Format (GIF), and is the most used lossless image compression format on the Internet
- **BMP** file format, also known as bitmap image file or device independent bitmap (DIB) file format or simply a bitmap, is a raster graphics image file format used to store

bitmap digital images, independently of the display device (such as a graphics adapter)

- **JPEG** file format (seen most often with the .jpg extension) is a commonly used method of lossy compression for digital images, particularly for those images produced by digital photography.
- **GIF** (Graphics Interchange Format) is a bitmap image format that was introduced by CompuServe in 1987 and has since come into widespread usage on the World Wide Web due to its wide support and portability.
- **TIFF** (Tagged Image File Format) is a computer file format for storing raster graphics images, popular among graphic artists, the publishing industry, and both amateur and professional photographers in general.

If using the **PNG** format, the control handles automatically its transparency / alpha blending, unless the [Opaque](#) property is True. For any other picture type, you can use any of the following to define the transparent region of the picture:

- [TransparentColorFrom](#), specifies the transparent color to define transparency part of the current picture (to).
- [TransparentColorTo](#), specifies the transparent color to define transparency part of the current picture (to).

The picture is displayed on the layer's background if both of the following:

- [Visible](#) property is True
- Name / [Value](#) property points to a valid picture

are accomplished.

The following properties can be used to load / import (manually or automatically) pictures to the layer's background:

- [PicturesPath](#) property, specifies the path to load pictures from.
- [PicturesName](#) property, specifies the expression that defines the name of the file from the PicturesPath folder to be loaded.
- Picture.Name / [Picture.Value](#) property of the Background.Picture object, defines the name of the file to be loaded (relative, absolute, encoded or Picture object)

The [PicturesPath](#) / [PicturesName](#) properties can be used to automatically loads files from a specified folder to be displayed on the layer's background.

For instance,

PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob",
defines default folder to load pictures from.

PicturesName = ""Layer` + str(value + 1) + `.png`", defines the name of the picture file

to be loaded by the layer with the index / value. It defines the names as: Layer1.png for the layer with the index 0, Layer2.png for the layer with the index 1, Layer3.png for the layer with the index 2, and so on.

The Picture.Name / [Picture.Value](#) property of the Picture object loads a picture / graphics to be displayed on the layer's background.

The following properties can be used to move / resize the picture on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

property LPicture.Opaque as Boolean

Indicates if the picture is opaque or transparent.

Type	Description
Boolean	A Boolean expression that specifies whether the current picture is shown as transparent or opaque.

By default, the Opaque property is False. The Opaque property indicates if the picture is shown as opaque or transparent.

If using the **PNG** format, the control handles automatically its transparency / alpha blending, unless the Opaque property is True, so in this case, any TransparentColorFrom or TransparentColorTo property has no effect.

For any other picture type, you can use any of the following to define the transparent region of the picture:

- [TransparentColorFrom](#), specifies the transparent color to define transparency part of the current picture (to).
- [TransparentColorTo](#), specifies the transparent color to define transparency part of the current picture (to).

The control supports almost all type of pictures like

- **PNG** (Portable Network Graphics) is a raster graphics file format that supports lossless data compression. PNG was created as an improved, non-patented replacement for Graphics Interchange Format (GIF), and is the most used lossless image compression format on the Internet
- **BMP** file format, also known as bitmap image file or device independent bitmap (DIB) file format or simply a bitmap, is a raster graphics image file format used to store bitmap digital images, independently of the display device (such as a graphics adapter)
- **JPEG** file format (seen most often with the .jpg extension) is a commonly used method of lossy compression for digital images, particularly for those images produced by digital photography.
- **GIF** (Graphics Interchange Format) is a bitmap image format that was introduced by CompuServe in 1987 and has since come into widespread usage on the World Wide Web due to its wide support and portability.
- **TIFF** (Tagged Image File Format) is a computer file format for storing raster graphics images, popular among graphic artists, the publishing industry, and both amateur and professional photographers in general.

property LPicture.Selectable as Boolean

Returns or sets a value that indicates whether the picture is selectable.

Type	Description
Boolean	A Boolean expression that specifies whether the picture on the layer's background is selectable.

By default, the Selectable property is True, so the picture is selectable on the layer's background. The Selectable property specifies whether the picture on the layer's background is selectable. Use the [Name](#) / [Value](#) property to specify a picture to be displayed on the layer's background. For instance, you can use Selectable property on False, to prevent selecting the picture on the layer's background. The [Selectable](#) property of the Background object, affects all the pictures / colors being shown on the layer's background. You can use the [Grayscale](#) property to show the entire layer in gray scale (disable state).

property LPicture.Top as String

Specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.

Type	Description
String	A String value that defines the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.

By default, the Top property is "0". You can use the Top property of the LPicture object to show the picture moved up or down.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.
- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.

For instance, the following sample shows the picture on a size of 64,64 in the center of the layer:

```
With .Background.Picture
.Width = "64"
.Height = "64"
.Left = "(width - 64)/2"
.Top = "(height - 64)/2"
End With
```

The Top property supports the following keywords:

- **pwidth**, specifies the width in pixels of the picture object
- **pheight**, specifies the height in pixels of the picture object
- **width**, specifies the width in pixels of the layer where the picture is displayed.
- **height**, specifies the height in pixels of the layer where the picture is displayed.

The Top property supports the following constants, operators and functions:

The constants are (DPI-Aware components):

- **dpi** (DPI constant), specifies the current DPI setting. and it indicates the minimum value between **dpix** and **dpiy** constants. For instance, if current DPI setting is 100%, the dpi constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpi returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%
- **dpix** (DPIX constant), specifies the current DPI setting on x-scale. For instance, if current DPI setting is 100%, the dpix constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpix returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%
- **dpiy** (DPIY constant), specifies the current DPI setting on y-scale. For instance, if current DPI setting is 100%, the dpiy constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpiy returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%

The supported binary arithmetic operators are:

- ***** (multiplicity operator), priority 5
- **/** (divide operator), priority 5
- **mod** (reminder operator), priority 5
- **+** (addition operator), priority 4 (concatenates two strings, if one of the operands is of string type)
- **-** (subtraction operator), priority 4

The supported unary boolean operators are:

- **not** (not operator), priority 3 (high priority)

The supported binary boolean operators are:

- **or** (or operator), priority 2
- **and** (or operator), priority 1

The supported binary boolean operators, all these with the same priority 0, are :

- **<** (less operator)
- **<=** (less or equal operator)
- **=** (equal operator)
- **!=** (not equal operator)
- **>=** (greater or equal operator)
- **>** (greater operator)

The supported binary range operators, all these with the same priority 5, are :

- **MIN** (min operator), indicates the minimum value, so a **MIN** b returns the value of a, if it is less than b, else it returns b. For instance, the expression value MIN 10 returns always a value greater than 10.
- **MAX** (max operator), indicates the maximum value, so a **MAX** b returns the value of a, if it is greater than b, else it returns b. For instance, the expression value MAX 100 returns always a value less than 100.

The supported binary operators, all these with the same priority 0, are :

- **:= (Store operator)**, stores the result of expression to variable. The syntax for := operator is

variable := expression

where variable is a integer between 0 and 9. You can use the **:=** operator to restore any stored variable (please make the difference between **:=** and **=:**). For instance, **(0:=dbl(value)) = 0 ? "zero" : =:0**, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the **:=** and **=:** are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

- **=: (Restore operator)**, restores the giving variable (previously saved using the store operator). The syntax for **=:** operator is

:= variable

where variable is a integer between 0 and 9. You can use the ***:=*** operator to store the value of any expression (please make the difference between ***:=*** and ***=***). For instance, ***(0:=dbl(value)) = 0 ? "zero" : :=0***, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the ***:=*** and ***=*** are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

The supported ternary operators, all these with the same priority 0, are :

- ***? (Immediate If operator)***, returns and executes one of two expressions, depending on the evaluation of an expression. The syntax for ***?*** operator is

expression ? true_part : false_part

, while it executes and returns the ***true_part*** if the expression is true, else it executes and returns the ***false_part***. For instance, the ***%0 = 1 ? 'One' : (%0 = 2 ? 'Two' : 'not found')*** returns 'One' if the value is 1, 'Two' if the value is 2, and 'not found' for any other value. A n-ary equivalent operation is the ***case()*** statement, which is available in newer versions of the component.

The supported n-ary operators are (with priority 5):

- ***array (at operator)***, returns the element from an array giving its index (0 base). The ***array*** operator returns empty if the element is found, else the associated element in the collection if it is found. The syntax for ***array*** operator is

expression array (c1,c2,c3,...cn)

, where the ***c1***, ***c2***, ... are constant elements. The constant elements could be numeric, date or string expressions. For instance the ***month(value)-1 array ('J','F','M','A','M','Jun','J','A','S','O','N','D')*** is equivalent with ***month(value)-1 case (default:"; 0:'J';1:'F';2:'M';3:'A';4:'M';5:'Jun';6:'J';7:'A';8:'S';9:'O';10:'N';11:'D')***.

- ***in (include operator)***, specifies whether an element is found in a set of constant elements. The ***in*** operator returns -1 (True) if the element is found, else 0 (false) is retrieved. The syntax for ***in*** operator is

expression in (c1,c2,c3,...cn)

, where the ***c1***, ***c2***, ... are constant elements. The constant elements could be numeric, date or string expressions. For instance the ***value in (11,22,33,44,13)*** is equivalent with ***(expression = 11) or (expression = 22) or (expression = 33) or (expression = 44) or***

(*expression* = 13). The *in* operator is not a time consuming as the equivalent *or* version is, so when you have large number of constant elements it is recommended using the *in* operator. Shortly, if the collection of elements has 1000 elements the *in* operator could take up to 8 operations in order to find if an element fits the set, else if the *or* statement is used, it could take up to 1000 operations to check, so by far, the *in* operator could save time on finding elements within a collection.

- ***switch*** (*switch operator*), returns the value being found in the collection, or a predefined value if the element is not found (default). The syntax for *switch* operator is

expression switch (default,c1,c2,c3,...,cn)

, where the *c1*, *c2*, ... are constant elements, and the *default* is a constant element being returned when the element is not found in the collection. The constant elements could be numeric, date or string expressions. The equivalent syntax is "*%0 = c 1 ? c 1 : (%0 = c 2 ? c 2 : (... ? . : default))*". The *switch* operator is very similar with the *in* operator excepts that the first element in the switch is always returned by the statement if the element is not found, while the returned value is the value itself instead -1. For instance, the *%0 switch ('not found',1,4,7,9,11)* gets 1, 4, 7, 9 or 11, or 'not found' for any other value. As the *in* operator the *switch* operator uses binary searches for fitting the element, so it is quicker than *iif* (immediate if operator) alternative.

- ***case()*** (*case operator*) returns and executes one of *n* expressions, depending on the evaluation of the expression (*IIF* - immediate IF operator is a binary *case()* operator). The syntax for *case()* operator is:

expression case ([default : default_expression ;] c1 : expression1 ; c2 : expression2 ; c3 : expression3 ;....)

If the default part is missing, the *case()* operator returns the value of the expression if it is not found in the collection of cases (*c1*, *c2*, ...). For instance, if the value of expression is not any of *c1*, *c2*, the *default_expression* is executed and returned. If the value of the expression is *c1*, then the *case()* operator executes and returns the *expression1*. The *default*, *c1*, *c2*, *c3*, ... must be constant elements as numbers, dates or strings. For instance, the *date(shortdate(value)) case (default:0 ; #1/1/2002#:1 ; #2/1/2002#:1; #4/1/2002#:1; #5/1/2002#:1)* indicates that only #1/1/2002#, #2/1/2002#, #4/1/2002# and #5/1/2002# dates returns 1, since the others returns 0. For instance the following sample specifies the hour being non-working for specified dates: *date(shortdate(value)) case(default:0;#4/1/2009# : hour(value) >= 6 and hour(value) <= 12 ; #4/5/2009# : hour(value) >= 7 and hour(value) <= 10 or hour(value) in(15,16,18,22); #5/1/2009# : hour(value) <= 8)* statement indicates the working hours for dates as follows:

- #4/1/2009#, from hours 06:00 AM to 12:00 PM
- #4/5/2009#, from hours 07:00 AM to 10:00 AM and hours 03:00PM, 04:00PM, 06:00PM and 10:00PM
- #5/1/2009#, from hours 12:00 AM to 08:00 AM

The *in*, *switch* and *case()* use binary search to look for elements so they are faster than using *iif* and *or* expressions. Obviously, the priority of the operations inside the expression is determined by () parenthesis and the priority for each operator.

The supported conversion unary operators are:

- **type** (unary operator) retrieves the type of the object. For instance *type(%1) = 8* specifies the cells (on the column 1) that contains string values.

Here's few predefined types:

- 0 - empty (not initialized)
- 1 - null
- 2 - short
- 3 - long
- 4 - float
- 5 - double
- 6 - currency
- 7 - date
- 8 - string
- 9 - object
- 10 - error
- 11 - boolean
- 12 - variant
- 13 - any
- 14 - decimal
- 16 - char
- 17 - byte
- 18 - unsigned short
- 19 - unsigned long
- 20 - long on 64 bits
- 21 - unsigned long on 64 bites
- **str** (unary operator) converts the expression to a string. The *str* operator converts the expression to a string. For instance, the *str(-12.54)* returns the string "-12.54".
- **dbl** (unary operator) converts the expression to a number. The *dbl* operator converts the expression to a number. For instance, the *dbl("12.54")* returns 12.54
- **date** (unary operator) converts the expression to a date, based on your regional settings. For instance, the *date(`)* gets the current date (no time included), the

date(now) gets the current date-time, while the *date("01/01/2001")* returns #1/1/2001#

- **dateS** (unary operator) converts the string expression to a date using the format MM/DD/YYYY HH:MM:SS. For instance, the *dateS("01/01/2001 14:00:00")* returns #1/1/2001 14:00:00#

Other known operators for numbers are:

- **int** (unary operator) retrieves the integer part of the number. For instance, the *int(12.54)* returns 12
- **round** (unary operator) rounds the number ie 1.2 gets 1, since 1.8 gets 2. For instance, the *round(12.54)* returns 13
- **floor** (unary operator) returns the largest number with no fraction part that is not greater than the value of its argument. For instance, the *floor(12.54)* returns 12
- **abs** (unary operator) retrieves the absolute part of the number ie -1 gets 1, 2 gets 2. For instance, the *abs(-12.54)* returns 12.54
- **sin** (unary operator) returns the sine of an angle of x radians. For instance, the *sin(3.14)* returns 0.001593.
- **cos** (unary operator) returns the cosine of an angle of x radians. For instance, the *cos(3.14)* returns -0.999999.
- **asin** (unary operator) returns the principal value of the arc sine of x, expressed in radians. For instance, the *2*asin(1)* returns the value of PI.
- **acos** (unary operator) returns the principal value of the arc cosine of x, expressed in radians. For instance, the *2*acos(0)* returns the value of PI
- **sqrt** (unary operator) returns the square root of x. For instance, the *sqrt(81)* returns 9.
- **currency** (unary operator) formats the giving number as a currency string, as indicated by the control panel. For instance, *currency(value)* displays the value using the current format for the currency ie, 1000 gets displayed as \$1,000.00, for US format.
- value **format** 'flags' (binary operator) formats the value with specified flags. If flags is empty, the number is displayed as shown in the field "Number" in the "Regional and Language Options" from the Control Panel. For instance the *1000 format "* displays 1,000.00 for English format, while 1.000,00 is displayed for German format. *1000 format '2|.|3|,'* will always displays 1,000.00 no matter of settings in the control panel. If formatting the number fails for some invalid parameter, the value is displayed with no formatting.

The ' flags' for format operator is a list of values separated by | character such as 'NumDigits|DecimalSep|Grouping|ThousandSep|NegativeOrder|LeadingZero' with the following meanings:

- *NumDigits* - specifies the number of fractional digits, If the flag is missing, the field "No. of digits after decimal" from "Regional and Language Options" is using.
- *DecimalSep* - specifies the decimal separator. If the flag is missing, the field

"Decimal symbol" from "Regional and Language Options" is using.

- **Grouping** - indicates the number of digits in each group of numbers to the left of the decimal separator. Values in the range 0 through 9 and 32 are valid. The most significant grouping digit indicates the number of digits in the least significant group immediately to the left of the decimal separator. Each subsequent grouping digit indicates the next significant group of digits to the left of the previous group. If the last value supplied is not 0, the remaining groups repeat the last group. Typical examples of settings for this member are: 0 to group digits as in 123456789.00; 3 to group digits as in 123,456,789.00; and 32 to group digits as in 12,34,56,789.00. If the flag is missing, the field "Digit grouping" from "Regional and Language Options" indicates the grouping flag.
- **ThousandSep** - specifies the thousand separator. If the flag is missing, the field "Digit grouping symbol" from "Regional and Language Options" is using.
- **NegativeOrder** - indicates the negative number mode. If the flag is missing, the field "Negative number format" from "Regional and Language Options" is using. The valid values are 0, 1, 2, 3 and 4 with the following meanings:
 - 0 - Left parenthesis, number, right parenthesis; for example, (1.1)
 - 1 - Negative sign, number; for example, -1.1
 - 2 - Negative sign, space, number; for example, - 1.1
 - 3 - Number, negative sign; for example, 1.1-
 - 4 - Number, space, negative sign; for example, 1.1 -
- **LeadingZero** - indicates if leading zeros should be used in decimal fields. If the flag is missing, the field "Display leading zeros" from "Regional and Language Options" is using. The valid values are 0, 1

Other known operators for strings are:

- **len** (unary operator) retrieves the number of characters in the string. For instance, the *len("Mihai")* returns 5.
- **lower** (unary operator) returns a string expression in lowercase letters. For instance, the *lower("MIHAI")* returns "mihai"
- **upper** (unary operator) returns a string expression in uppercase letters. For instance, the *upper("mihai")* returns "MIHAI"
- **proper** (unary operator) returns from a character expression a string capitalized as appropriate for proper names. For instance, the *proper("mihai")* returns "Mihai"
- **ltrim** (unary operator) removes spaces on the left side of a string. For instance, the *ltrim(" mihai")* returns "mihai"
- **rtrim** (unary operator) removes spaces on the right side of a string. For instance, the *rtrim("mihai ")* returns "mihai"
- **trim** (unary operator) removes spaces on both sides of a string. For instance, the *trim(" mihai ")* returns "mihai"
- **reverse** (unary operator) reverses the order of the characters in the string a. For instance, the *reverse("Mihai")* returns "iahIM"

- **startswith** (binary operator) specifies whether a string starts with specified string (0 if not found, -1 if found). For instance *"Mihai" startswith "Mi"* returns -1
- **endwith** (binary operator) specifies whether a string ends with specified string (0 if not found, -1 if found). For instance *"Mihai" endwith "ai"* returns -1
- **contains** (binary operator) specifies whether a string contains another specified string (0 if not found, -1 if found). For instance *"Mihai" contains "ha"* returns -1
- **left** (binary operator) retrieves the left part of the string. For instance *"Mihai" left 2* returns "Mi".
- **right** (binary operator) retrieves the right part of the string. For instance *"Mihai" right 2* returns "ai"
- a **lfind** b (binary operator) The a lfind b (binary operator) searches the first occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" lfind "C"* returns 2
- a **rfind** b (binary operator) The a rfind b (binary operator) searches the last occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" rfind "C"* returns 5.
- a **mid** b (binary operator) retrieves the middle part of the string a starting from b (1 means first position, and so on). For instance *"Mihai" mid 2* returns "ihai"
- a **count** b (binary operator) retrieves the number of occurrences of the b in a. For instance *"Mihai" count "i"* returns 2.
- a **replace** b with c (double binary operator) replaces in a the b with c, and gets the result. For instance, the *"Mihai" replace "i" with ""* returns "Mha" string, as it replaces all "i" with nothing.
- a **split** b, splits the a using the separator b, and returns an array. For instance, the *weekday(value) array 'Sun Mon Thu Wed Thu Fri Sat' split ' '* gets the weekday as string. This operator can be used with the array.

Other known operators for dates are:

- **time** (unary operator) retrieves the time of the date in string format, as specified in the control's panel. For instance, the *time(#1/1/2001 13:00#)* returns "1:00:00 PM"
- **timeF** (unary operator) retrieves the time of the date in string format, as "HH:MM:SS". For instance, the *timeF(#1/1/2001 13:00#)* returns "13:00:00"
- **shortdate** (unary operator) formats a date as a date string using the short date format, as specified in the control's panel. For instance, the *shortdate(#1/1/2001 13:00#)* returns "1/1/2001"
- **shortdateF** (unary operator) formats a date as a date string using the "MM/DD/YYYY" format. For instance, the *shortdateF(#1/1/2001 13:00#)* returns "01/01/2001"
- **dateF** (unary operator) converts the date expression to a string expression in "MM/DD/YYYY HH:MM:SS" format. For instance, the *dateF(#01/01/2001 14:00:00#)* returns #01/01/2001 14:00:00#

- **longdate** (unary operator) formats a date as a date string using the long date format, as specified in the control's panel. For instance, the *longdate(#1/1/2001 13:00#)* returns "Monday, January 01, 2001"
- **year** (unary operator) retrieves the year of the date (100,...,9999). For instance, the *year(#12/31/1971 13:14:15#)* returns 1971
- **month** (unary operator) retrieves the month of the date (1, 2,...,12). For instance, the *month(#12/31/1971 13:14:15#)* returns 12.
- **day** (unary operator) retrieves the day of the date (1, 2,...,31). For instance, the *day(#12/31/1971 13:14:15#)* returns 31
- **yearday** (unary operator) retrieves the number of the day in the year, or the days since January 1st (0, 1,...,365). For instance, the *yearday(#12/31/1971 13:14:15#)* returns 365
- **weekday** (unary operator) retrieves the number of days since Sunday (0 - Sunday, 1 - Monday,..., 6 - Saturday). For instance, the *weekday(#12/31/1971 13:14:15#)* returns 5.
- **hour** (unary operator) retrieves the hour of the date (0, 1, ..., 23). For instance, the *hour(#12/31/1971 13:14:15#)* returns 13
- **min** (unary operator) retrieves the minute of the date (0, 1, ..., 59). For instance, the *min(#12/31/1971 13:14:15#)* returns 14
- **sec** (unary operator) retrieves the second of the date (0, 1, ..., 59). For instance, the *sec(#12/31/1971 13:14:15#)* returns 15

The Exontrol's [eXPression](#) component is a syntax-editor that helps you to define, view, edit and evaluate expressions. Using the eXPression component you can easily view or check if the expression you have used is syntactically correct, and you can evaluate what is the result you get giving different values to be tested. The Exontrol's eXPression component can be used as an user-editor, to configure your applications.

property LPicture.TransparentColorFrom as Color

Specifies the transparent color to define transparency part of the current picture (to).

Type	Description
Color	A Color expression that defines the transparent color.

By default, the TransparentColorFrom property is -1, which indicates that the control's [TransparentColorFrom](#) property defines the color to be shown as transparent on the current picture. The [Opaque](#) property indicates if the picture is shown as opaque or transparent.

The TransparentColorFrom / TransparentColorTo properties have effect it:

- [Opaque](#) property is False (by default)
- picture's attribute does **not** include the PICTURE_TRANSPARENT flag (for instance a PNG picture with transparency, includes the PICTURE_TRANSPARENT flag)
- TransparentColorFrom / TransparentColorTo properties points to valid colors (different than -1 value). For instance, if one property is defined and the other is -1, the first one defines the transparent pixels, while if both are specified and points to value different than -1, any pixel between them is considered as transparent.

If The TransparentColorFrom / TransparentColorTo properties have effect, any picture where these apply defines the pixels as:

- any pixel with a color between TransparentColorFrom and TransparentColorTo is defined as transparent
- any other pixel that's not transparent is opaque.

The control supports almost all type of pictures like

- **PNG** (Portable Network Graphics) is a raster graphics file format that supports lossless data compression. PNG was created as an improved, non-patented replacement for Graphics Interchange Format (GIF), and is the most used lossless image compression format on the Internet
- **BMP** file format, also known as bitmap image file or device independent bitmap (DIB) file format or simply a bitmap, is a raster graphics image file format used to store bitmap digital images, independently of the display device (such as a graphics adapter)
- **JPEG** file format (seen most often with the .jpg extension) is a commonly used method of lossy compression for digital images, particularly for those images produced by digital photography.
- **GIF** (Graphics Interchange Format) is a bitmap image format that was introduced by CompuServe in 1987 and has since come into widespread usage on the World Wide Web due to its wide support and portability.
- **TIFF** (Tagged Image File Format) is a computer file format for storing raster graphics

images, popular among graphic artists, the publishing industry, and both amateur and professional photographers in general.

If using the **PNG** format, the control handles automatically its transparency / alpha blending (if exists), unless the [Opaque](#) property is True, so in this case, any TransparentColorFrom or TransparentColorTo property has no effect.

For any other picture type, you can use any of the following to define the transparent region of the picture:

- TransparentColorFrom, specifies the transparent color to define transparency part of the current picture (to).
- [TransparentColorTo](#), specifies the transparent color to define transparency part of the current picture (to).

property LPicture.TransparentColorTo as Color

Specifies the transparent color to define transparency part of the current picture (to).

Type	Description
Color	A Color expression that defines the transparent color.

By default, the TransparentColorTo property is -1, which indicates that the control's [TransparentColorTo](#) property defines the color to be shown as transparent on the current picture. The [Opaque](#) property indicates if the picture is shown as opaque or transparent.

The TransparentColorFrom / TransparentColorTo properties have effect it:

- [Opaque](#) property is False (by default)
- picture's attribute does **not** include the PICTURE_TRANSPARENT flag (for instance a PNG picture with transparency, includes the PICTURE_TRANSPARENT flag)
- TransparentColorFrom / TransparentColorTo properties points to valid colors (different than -1 value). For instance, if one property is defined and the other is -1, the first one defines the transparent pixels, while if both are specified and points to value different than -1, any pixel between them is considered as transparent.

If The TransparentColorFrom / TransparentColorTo properties have effect, any picture where these apply defines the pixels as:

- any pixel with a color between TransparentColorFrom and TransparentColorTo is defined as transparent
- any other pixel that's not transparent is opaque.

The control supports almost all type of pictures like

- **PNG** (Portable Network Graphics) is a raster graphics file format that supports lossless data compression. PNG was created as an improved, non-patented replacement for Graphics Interchange Format (GIF), and is the most used lossless image compression format on the Internet
- **BMP** file format, also known as bitmap image file or device independent bitmap (DIB) file format or simply a bitmap, is a raster graphics image file format used to store bitmap digital images, independently of the display device (such as a graphics adapter)
- **JPEG** file format (seen most often with the .jpg extension) is a commonly used method of lossy compression for digital images, particularly for those images produced by digital photography.
- **GIF** (Graphics Interchange Format) is a bitmap image format that was introduced by CompuServe in 1987 and has since come into widespread usage on the World Wide Web due to its wide support and portability.
- **TIFF** (Tagged Image File Format) is a computer file format for storing raster graphics

images, popular among graphic artists, the publishing industry, and both amateur and professional photographers in general.

If using the **PNG** format, the control handles automatically its transparency / alpha blending (if saved with transparency), unless the [Opaque](#) property is True, so in this case, any TransparentColorFrom or TransparentColorTo property has no effect.

For any other picture type, you can use any of the following to define the transparent region of the picture:

- [TransparentColorFrom](#), specifies the transparent color to define transparency part of the current picture (to).
- TransparentColorTo, specifies the transparent color to define transparency part of the current picture (to).

property LPicture.Value as Variant

Indicates the picture to be shown on the layer's background.

Type	Description
Variant	<p>The Value property could be one of the following:</p> <ul style="list-style-type: none">• A String expression indicates:<ul style="list-style-type: none">◦ a name of a picture file in the PicturePath folder. For instance, Name = "Layer1.png", loads the Layer1.png file if found in the PicturePath folder.◦ a picture file including its absolute path. For instance, Name = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\K loads the Layer1.png file from absolute path◦ a key of the HTML picture, previously loaded by the HTMLPicture method. For instance, Name = "pic1", loads the HTML picture with the key pic1, so the pic1 should be load previously with a HTMLPicture call like HTMLPicture("pic1") = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\K◦ an encode BASE64 string of a picture file. The Exontrol's ExImages Tool encode/decode BASE64 strings from/to pictures. In this case, the string starts with "gB..", "gC.." and so on.• A Picture object that indicates the picture to be displayed. For instance, Name = LoadPicture("picture.jpg")

By default, the [Name](#) / Value property is initialized by evaluating the control's [PicturesName](#) property, whose **value** keyword is replaced by the [Index](#) of the current layer. The [Name](#) / Value property are equivalents, so use any of them do the same.

The control supports almost all type of pictures like

- **PNG** (Portable Network Graphics) is a raster graphics file format that supports lossless data compression. PNG was created as an improved, non-patented replacement for Graphics Interchange Format (GIF), and is the most used lossless image compression format on the Internet
- **BMP** file format, also known as bitmap image file or device independent bitmap (DIB) file format or simply a bitmap, is a raster graphics image file format used to store

bitmap digital images, independently of the display device (such as a graphics adapter)

- **JPEG** file format (seen most often with the .jpg extension) is a commonly used method of lossy compression for digital images, particularly for those images produced by digital photography.
- **GIF** (Graphics Interchange Format) is a bitmap image format that was introduced by CompuServe in 1987 and has since come into widespread usage on the World Wide Web due to its wide support and portability.
- **TIFF** (Tagged Image File Format) is a computer file format for storing raster graphics images, popular among graphic artists, the publishing industry, and both amateur and professional photographers in general.

If using the **PNG** format, the control handles automatically its transparency / alpha blending, unless the [Opaque](#) property is True. For any other picture type, you can use any of the following to define the transparent region of the picture:

- [TransparentColorFrom](#), specifies the transparent color to define transparency part of the current picture (to).
- [TransparentColorTo](#), specifies the transparent color to define transparency part of the current picture (to).

The picture is displayed on the layer's background if both of the following:

- [Visible](#) property is True
- [Name](#) / Value property points to a valid picture

are accomplished.

The following properties can be used to load / import (manually or automatically) pictures to the layer's background:

- [PicturesPath](#) property, specifies the path to load pictures from.
- [PicturesName](#) property, specifies the expression that defines the name of the file from the PicturesPath folder to be loaded.
- [Picture.Name](#) / Picture.Value property of the Background.Picture object, defines the name of the file to be loaded (relative, absolute, encoded or Picture object)

The [PicturesPath](#) / [PicturesName](#) properties can be used to automatically loads files from a specified folder to be displayed on the layer's background.

For instance,

PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob",
defines default folder to load pictures from.

PicturesName = ""Layer` + str(value + 1) + `.png`", defines the name of the picture file

to be loaded by the layer with the index / value. It defines the names as: Layer1.png for the layer with the index 0, Layer2.png for the layer with the index 1, Layer3.png for the layer with the index 2, and so on.

The [Picture.Name](#) / Picture.Value property of the Picture object loads a picture / graphics to be displayed on the layer's background.

The following properties can be used to move / resize the picture on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- [Width](#), specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

property LPicture.Visible as Boolean

Specifies if the picture is shown or hidden on the layer's background.

Type	Description
Boolean	A Boolean expression that specifies whether the picture is visible or hidden.

By default, the Visible property is True, so the picture is visible on the layer's background. Use the [Name](#) / [Value](#) property to specify a picture to be displayed on the layer's background. For instance, you can use Visible property on False, to prevent showing the picture on the layer's background. The [Selectable](#) property specifies whether the picture on the layer's background is selectable. The [Visible](#) property of the Background object, affects all the pictures / colors being shown on the layer's background.

The picture is displayed on the layer's background if both of the following:

- Visible property is True
- [Name](#) / [Value](#) property points to a valid picture

are accomplished.

property LPicture.Width as String

Specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.

Type	Description
String	A String value that indicates the expression relative to the view/current picture, to determine the width to show the current picture on the background.

By default, the Width property is "**width**", that specifies the width in pixels of the layer where the picture is displayed.. You can use the Width property of the LPicture object to show the picture with a different width. The [LayerAutoSize](#) property resizes all layers based on the picture of the first layer.

The following properties can be used to move / resize the **picture** on the layer's background:

- [DisplayAs](#), retrieves or sets a value that indicates the way how the graphic is displayed on the layer's background.
- [Left](#), specifies the expression relative to the view/current picture, to determine the x-position to show the current picture on the background.
- [Top](#), specifies the expression relative to the view/current picture, to determine the y-position to show the current picture on the background.
- Width, specifies the expression relative to the view/current picture, to determine the width to show the current picture on the background.
- [Height](#), specifies the expression relative to the view/current picture, to determine the height to show the current picture on the background.

The following properties determines the position / size / offset of the **layer**:

- [Left](#), specifies the expression relative to the view, to determine the x-position to show the current layer on the control.
- [Top](#), specifies the expression relative to the view, to determine the y-position to show the current layer on the control.
- [Width](#), specifies the expression relative to the view, to determine the width to show the current layer on the control.
- [Height](#), specifies the expression relative to the view, to determine the height to show the current layer on the control.

You can use the following properties to offset the view (background + foreground) inside the layer:

- [OffsetX](#), gets or sets a value that indicates x-offset of the layer.

- [OffsetY](#), gets or sets a value that indicates y-offset of the layer.

For instance, the following sample shows the picture on a size of 64,64 in the center of the layer:

```
With .Background.Picture
.Width = "64"
.Height = "64"
.Left = "(width - 64)/2"
.Top = "(height - 64)/2"
End With
```

The Width property supports the following keywords:

- **pwidth**, specifies the width in pixels of the picture object
- **pheight**, specifies the height in pixels of the picture object
- **width**, specifies the width in pixels of the layer where the picture is displayed.
- **height**, specifies the height in pixels of the layer where the picture is displayed.

The Width property supports the following constants, operators and functions:

The constants are (DPI-Aware components):

- **dpi** (DPI constant), specifies the current DPI setting. and it indicates the minimum value between **dpix** and **dpiy** constants. For instance, if current DPI setting is 100%, the dpi constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpi returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%
- **dpix** (DPIX constant), specifies the current DPI setting on x-scale. For instance, if current DPI setting is 100%, the dpix constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpix returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%
- **dpiy** (DPIY constant), specifies the current DPI setting on y-scale. For instance, if current DPI setting is 100%, the dpiy constant returns 1, if 150% it returns 1.5, and so on. For instance, the expression value * dpiy returns the value if the DPI setting is 100%, or value * 1.5 in case, the DPI setting is 150%

The supported binary arithmetic operators are:

- ***** (multiplicity operator), priority 5
- **/** (divide operator), priority 5
- **mod** (reminder operator), priority 5
- **+** (addition operator), priority 4 (concatenates two strings, if one of the operands is

of string type)

- - (subtraction operator), priority 4

The supported unary boolean operators are:

- **not** (not operator), priority 3 (high priority)

The supported binary boolean operators are:

- **or** (or operator), priority 2
- **and** (and operator), priority 1

The supported binary boolean operators, all these with the same priority 0, are :

- < (less operator)
- <= (less or equal operator)
- = (equal operator)
- != (not equal operator)
- >= (greater or equal operator)
- > (greater operator)

The supported binary range operators, all these with the same priority 5, are :

- **MIN** (min operator), indicates the minimum value, so a **MIN** b returns the value of a, if it is less than b, else it returns b. For instance, the expression value MIN 10 returns always a value greater than 10.
- **MAX** (max operator), indicates the maximum value, so a **MAX** b returns the value of a, if it is greater than b, else it returns b. For instance, the expression value MAX 100 returns always a value less than 100.

The supported binary operators, all these with the same priority 0, are :

- **:= (Store operator)**, stores the result of expression to variable. The syntax for := operator is

variable := expression

where variable is a integer between 0 and 9. You can use the **:=** operator to restore any stored variable (please make the difference between **:=** and **=**). For instance, **(0:=dbl(value)) = 0 ? "zero" : :=0**, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the **:=** and **=** are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

- **=: (Restore operator)**, restores the giving variable (previously saved using the store operator). The syntax for =: operator is

=: variable

where variable is a integer between 0 and 9. You can use the := operator to store the value of any expression (please make the difference between := and =:). For instance, $(0:=dbl(value)) = 0 ? "zero" : =:0$, stores the value converted to double, and prints zero if it is 0, else the converted number. Please pay attention that the := and =: are two distinct operators, the first for storing the result into a variable, while the second for restoring the variable

The supported ternary operators, all these with the same priority 0, are :

- **? (Immediate If operator)**, returns and executes one of two expressions, depending on the evaluation of an expression. The syntax for ? operator is

expression ? true_part : false_part

, while it executes and returns the true_part if the expression is true, else it executes and returns the false_part. For instance, the $\%0 = 1 ? 'One' : (\%0 = 2 ? 'Two' : 'not found')$ returns 'One' if the value is 1, 'Two' if the value is 2, and 'not found' for any other value. A n-ary equivalent operation is the case() statement, which is available in newer versions of the component.

The supported n-ary operators are (with priority 5):

- **array (at operator)**, returns the element from an array giving its index (0 base). The array operator returns empty if the element is found, else the associated element in the collection if it is found. The syntax for array operator is

expression array (c1,c2,c3,...cn)

, where the c1, c2, ... are constant elements. The constant elements could be numeric, date or string expressions. For instance the *month(value)-1 array* ('J','F','M','A','M','Jun','J','A','S','O','N','D') is equivalent with *month(value)-1 case* (default:"; 0:'J';1:'F';2:'M';3:'A';4:'M';5:'Jun';6:'J';7:'A';8:'S';9:'O';10:'N';11:'D').

- **in (include operator)**, specifies whether an element is found in a set of constant elements. The in operator returns -1 (True) if the element is found, else 0 (false) is retrieved. The syntax for in operator is

expression in (c1,c2,c3,...cn)

, where the c_1, c_2, \dots are constant elements. The constant elements could be numeric, date or string expressions. For instance the *value in (11,22,33,44,13)* is equivalent with *(expression = 11) or (expression = 22) or (expression = 33) or (expression = 44) or (expression = 13)*. The *in* operator is not a time consuming as the equivalent *or* version is, so when you have large number of constant elements it is recommended using the *in* operator. Shortly, if the collection of elements has 1000 elements the *in* operator could take up to 8 operations in order to find if an element fits the set, else if the *or* statement is used, it could take up to 1000 operations to check, so by far, the *in* operator could save time on finding elements within a collection.

- ***switch*** (*switch operator*), returns the value being found in the collection, or a predefined value if the element is not found (default). The syntax for *switch* operator is

expression switch (default,c1,c2,c3,...,cn)

, where the c_1, c_2, \dots are constant elements, and the default is a constant element being returned when the element is not found in the collection. The constant elements could be numeric, date or string expressions. The equivalent syntax is " $\%0 = c_1 ? c_1 : (\%0 = c_2 ? c_2 : (\dots ? \dots : default))$ ". The *switch* operator is very similar with the *in* operator excepts that the first element in the switch is always returned by the statement if the element is not found, while the returned value is the value itself instead -1. For instance, the $\%0 \text{ switch } ('not\ found', 1, 4, 7, 9, 11)$ gets 1, 4, 7, 9 or 11, or 'not found' for any other value. As the *in* operator the *switch* operator uses binary searches for fitting the element, so it is quicker than *iif* (immediate if operator) alternative.

- ***case()*** (*case operator*) returns and executes one of n expressions, depending on the evaluation of the expression (*IIF* - immediate IF operator is a binary *case()* operator). The syntax for *case()* operator is:

expression case ([default : default_expression ;] c1 : expression1 ; c2 : expression2 ; c3 : expression3 ;....)

If the default part is missing, the *case()* operator returns the value of the expression if it is not found in the collection of cases (c_1, c_2, \dots). For instance, if the value of expression is not any of c_1, c_2, \dots the *default_expression* is executed and returned. If the value of the expression is c_1 , then the *case()* operator executes and returns the *expression1*. The *default, c1, c2, c3, ...* must be constant elements as numbers, dates or strings. For instance, the *date(shortdate(value)) case (default:0 ; #1/1/2002#:1 ; #2/1/2002#:1; #4/1/2002#:1; #5/1/2002#:1)* indicates that only #1/1/2002#, #2/1/2002#, #4/1/2002# and #5/1/2002# dates returns 1, since the others returns 0. For instance the following sample specifies the hour being non-working for specified dates: *date(shortdate(value)) case(default:0;#4/1/2009# : hour(value) >= 6 and hour(value) <= 12 ; #4/5/2009# : hour(value) >= 7 and hour(value) <= 10 or*

hour(value) in(15,16,18,22); #5/1/2009# : hour(value) <= 8) statement indicates the working hours for dates as follows:

- *#4/1/2009#*, from hours 06:00 AM to 12:00 PM
- *#4/5/2009#*, from hours 07:00 AM to 10:00 AM and hours 03:00PM, 04:00PM, 06:00PM and 10:00PM
- *#5/1/2009#*, from hours 12:00 AM to 08:00 AM

The *in*, *switch* and *case()* use binary search to look for elements so they are faster than using *if* and *or* expressions. Obviously, the priority of the operations inside the expression is determined by () parenthesis and the priority for each operator.

The supported conversion unary operators are:

- **type** (unary operator) retrieves the type of the object. For instance *type(%1) = 8* specifies the cells (on the column 1) that contains string values.

Here's few predefined types:

- 0 - empty (not initialized)
- 1 - null
- 2 - short
- 3 - long
- 4 - float
- 5 - double
- 6 - currency
- 7 - date
- 8 - string
- 9 - object
- 10 - error
- 11 - boolean
- 12 - variant
- 13 - any
- 14 - decimal
- 16 - char
- 17 - byte
- 18 - unsigned short
- 19 - unsigned long
- 20 - long on 64 bits
- 21 - unsigned long on 64 bites
- **str** (unary operator) converts the expression to a string. The *str* operator converts the expression to a string. For instance, the *str(-12.54)* returns the string "-12.54".
- **dbl** (unary operator) converts the expression to a number. The *dbl* operator converts the expression to a number. For instance, the *dbl("12.54")* returns 12.54

- **date** (unary operator) converts the expression to a date, based on your regional settings. For instance, the *date``* gets the current date (no time included), the *date`now`* gets the current date-time, while the *date("01/01/2001")* returns #1/1/2001#
- **dateS** (unary operator) converts the string expression to a date using the format MM/DD/YYYY HH:MM:SS. For instance, the *dateS("01/01/2001 14:00:00")* returns #1/1/2001 14:00:00#

Other known operators for numbers are:

- **int** (unary operator) retrieves the integer part of the number. For instance, the *int(12.54)* returns 12
- **round** (unary operator) rounds the number ie 1.2 gets 1, since 1.8 gets 2. For instance, the *round(12.54)* returns 13
- **floor** (unary operator) returns the largest number with no fraction part that is not greater than the value of its argument. For instance, the *floor(12.54)* returns 12
- **abs** (unary operator) retrieves the absolute part of the number ie -1 gets 1, 2 gets 2. For instance, the *abs(-12.54)* returns 12.54
- **sin** (unary operator) returns the sine of an angle of x radians. For instance, the *sin(3.14)* returns 0.001593.
- **cos** (unary operator) returns the cosine of an angle of x radians. For instance, the *cos(3.14)* returns -0.999999.
- **asin** (unary operator) returns the principal value of the arc sine of x, expressed in radians. For instance, the *2*asin(1)* returns the value of PI.
- **acos** (unary operator) returns the principal value of the arc cosine of x, expressed in radians. For instance, the *2*acos(0)* returns the value of PI
- **sqrt** (unary operator) returns the square root of x. For instance, the *sqrt(81)* returns 9.
- **currency** (unary operator) formats the giving number as a currency string, as indicated by the control panel. For instance, *currency(value)* displays the value using the current format for the currency ie, 1000 gets displayed as \$1,000.00, for US format.
- value **format** 'flags' (binary operator) formats the value with specified flags. If flags is empty, the number is displayed as shown in the field "Number" in the "Regional and Language Options" from the Control Panel. For instance the *1000 format "* displays 1,000.00 for English format, while 1.000,00 is displayed for German format. *1000 format '2|.|3|,'* will always displays 1,000.00 no matter of settings in the control panel. If formatting the number fails for some invalid parameter, the value is displayed with no formatting.

The ' flags' for format operator is a list of values separated by | character such as 'NumDigits|DecimalSep|Grouping|ThousandSep|NegativeOrder|LeadingZero' with the following meanings:

- *NumDigits* - specifies the number of fractional digits, If the flag is missing, the field "No. of digits after decimal" from "Regional and Language Options" is using.
- *DecimalSep* - specifies the decimal separator. If the flag is missing, the field "Decimal symbol" from "Regional and Language Options" is using.
- *Grouping* - indicates the number of digits in each group of numbers to the left of the decimal separator. Values in the range 0 through 9 and 32 are valid. The most significant grouping digit indicates the number of digits in the least significant group immediately to the left of the decimal separator. Each subsequent grouping digit indicates the next significant group of digits to the left of the previous group. If the last value supplied is not 0, the remaining groups repeat the last group. Typical examples of settings for this member are: 0 to group digits as in 123456789.00; 3 to group digits as in 123,456,789.00; and 32 to group digits as in 12,34,56,789.00. If the flag is missing, the field "Digit grouping" from "Regional and Language Options" indicates the grouping flag.
- *ThousandSep* - specifies the thousand separator. If the flag is missing, the field "Digit grouping symbol" from "Regional and Language Options" is using.
- *NegativeOrder* - indicates the negative number mode. If the flag is missing, the field "Negative number format" from "Regional and Language Options" is using. The valid values are 0, 1, 2, 3 and 4 with the following meanings:
 - 0 - Left parenthesis, number, right parenthesis; for example, (1.1)
 - 1 - Negative sign, number; for example, -1.1
 - 2 - Negative sign, space, number; for example, - 1.1
 - 3 - Number, negative sign; for example, 1.1-
 - 4 - Number, space, negative sign; for example, 1.1 -
- *LeadingZero* - indicates if leading zeros should be used in decimal fields. If the flag is missing, the field "Display leading zeros" from "Regional and Language Options" is using. The valid values are 0, 1

Other known operators for strings are:

- **len** (unary operator) retrieves the number of characters in the string. For instance, the *len("Mihai")* returns 5.
- **lower** (unary operator) returns a string expression in lowercase letters. For instance, the *lower("MIHAI")* returns "mihai"
- **upper** (unary operator) returns a string expression in uppercase letters. For instance, the *upper("mihai")* returns "MIHAI"
- **proper** (unary operator) returns from a character expression a string capitalized as appropriate for proper names. For instance, the *proper("mihai")* returns "Mihai"
- **ltrim** (unary operator) removes spaces on the left side of a string. For instance, the *ltrim(" mihai")* returns "mihai"
- **rtrim** (unary operator) removes spaces on the right side of a string. For instance, the *rtrim("mihai ")* returns "mihai"
- **trim** (unary operator) removes spaces on both sides of a string. For instance, the

trim(" mihai ") returns "mihai"

- **reverse** (unary operator) reverses the order of the characters in the string a. For instance, the *reverse("Mihai")* returns "iahIM"
- **startswith** (binary operator) specifies whether a string starts with specified string (0 if not found, -1 if found). For instance *"Mihai" startwith "Mi"* returns -1
- **endwith** (binary operator) specifies whether a string ends with specified string (0 if not found, -1 if found). For instance *"Mihai" endwith "ai"* returns -1
- **contains** (binary operator) specifies whether a string contains another specified string (0 if not found, -1 if found). For instance *"Mihai" contains "ha"* returns -1
- **left** (binary operator) retrieves the left part of the string. For instance *"Mihai" left 2* returns "Mi".
- **right** (binary operator) retrieves the right part of the string. For instance *"Mihai" right 2* returns "ai"
- a **lfind** b (binary operator) The a lfind b (binary operator) searches the first occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" lfind "C"* returns 2
- a **rfind** b (binary operator) The a rfind b (binary operator) searches the last occurrence of the string b within string a, and returns -1 if not found, or the position of the result (zero-index). For instance *"ABCABC" rfind "C"* returns 5.
- a **mid** b (binary operator) retrieves the middle part of the string a starting from b (1 means first position, and so on). For instance *"Mihai" mid 2* returns "ihai"
- a **count** b (binary operator) retrieves the number of occurrences of the b in a. For instance *"Mihai" count "i"* returns 2.
- a **replace b with c** (double binary operator) replaces in a the b with c, and gets the result. For instance, the *"Mihai" replace "i" with ""* returns "Mha" string, as it replaces all "i" with nothing.
- a **split** b, splits the a using the separator b, and returns an array. For instance, the *weekday(value) array 'Sun Mon Thu Wed Thu Fri Sat' split ' '* gets the weekday as string. This operator can be used with the array.

Other known operators for dates are:

- **time** (unary operator) retrieves the time of the date in string format, as specified in the control's panel. For instance, the *time(#1/1/2001 13:00#)* returns "1:00:00 PM"
- **timeF** (unary operator) retrieves the time of the date in string format, as "HH:MM:SS". For instance, the *timeF(#1/1/2001 13:00#)* returns "13:00:00"
- **shortdate** (unary operator) formats a date as a date string using the short date format, as specified in the control's panel. For instance, the *shortdate(#1/1/2001 13:00#)* returns "1/1/2001"
- **shortdateF** (unary operator) formats a date as a date string using the "MM/DD/YYYY" format. For instance, the *shortdateF(#1/1/2001 13:00#)* returns "01/01/2001"

- **dateF** (unary operator) converts the date expression to a string expression in "MM/DD/YYYY HH:MM:SS" format. For instance, the *dateF(#01/01/2001 14:00:00#)* returns #01/01/2001 14:00:00#
- **longdate** (unary operator) formats a date as a date string using the long date format, as specified in the control's panel. For instance, the *longdate(#1/1/2001 13:00#)* returns "Monday, January 01, 2001"
- **year** (unary operator) retrieves the year of the date (100,...,9999). For instance, the *year(#12/31/1971 13:14:15#)* returns 1971
- **month** (unary operator) retrieves the month of the date (1, 2,...,12). For instance, the *month(#12/31/1971 13:14:15#)* returns 12.
- **day** (unary operator) retrieves the day of the date (1, 2,...,31). For instance, the *day(#12/31/1971 13:14:15#)* returns 31
- **yearday** (unary operator) retrieves the number of the day in the year, or the days since January 1st (0, 1,...,365). For instance, the *yearday(#12/31/1971 13:14:15#)* returns 365
- **weekday** (unary operator) retrieves the number of days since Sunday (0 - Sunday, 1 - Monday,..., 6 - Saturday). For instance, the *weekday(#12/31/1971 13:14:15#)* returns 5.
- **hour** (unary operator) retrieves the hour of the date (0, 1, ..., 23). For instance, the *hour(#12/31/1971 13:14:15#)* returns 13
- **min** (unary operator) retrieves the minute of the date (0, 1, ..., 59). For instance, the *min(#12/31/1971 13:14:15#)* returns 14
- **sec** (unary operator) retrieves the second of the date (0, 1, ..., 59). For instance, the *sec(#12/31/1971 13:14:15#)* returns 15

The Exontrol's [eXPression](#) component is a syntax-editor that helps you to define, view, edit and evaluate expressions. Using the eXPression component you can easily view or check if the expression you have used is syntactically correct, and you can evaluate what is the result you get giving different values to be tested. The Exontrol's eXPression component can be used as an user-editor, to configure your applications.

ExGauge events

The eXGauge / eXLayers library provides graphics capabilities to visually display and edit the amount, level, or contents of something. The view can show one or more layers, where each layer can display one or more transparent pictures, HTML captions which can be clipped, moved, rotated or combination of them, by dragging the mouse, rolling the mouse wheel, or using the keyboard. Using the eXGauge / eXLayers library you can easily simulate any gauges, thermometers, meters, clocks, buttons, sliders, scales, knobs, dials, switches, progress, status, indicators, LEDs, and so on.

The eXGauge supports the following events:

Name	Description
AnchorClick	Occurs when an anchor element is clicked.
Change	Occurs when the layer's value is changed.
Click	Occurs when the user presses and then releases the left mouse button over the control.
DbClick	Occurs when the user dblclk the left mouse button over an object.
Drag	Notifies that the user drags the layer.
DragEnd	Occurs once the user ends dragging a layer.
DragStart	Occurs once the user starts dragging a layer.
Event	Notifies the application once the control fires an event.
KeyDown	Occurs when the user presses a key while an object has the focus.
KeyPress	Occurs when the user presses and releases an ANSI key.
KeyUp	Occurs when the user releases a key while an object has the focus.
MouseDown	Occurs when the user presses a mouse button.
MouseIn	Notifies that the cursor enters the layer.
MouseMove	Occurs when the user moves the mouse.
MouseOut	Notifies that the cursor exits the layer.
MouseUp	Occurs when the user releases a mouse button.
MouseWheel	Occurs when the mouse wheel moves while the control has focus
RClick	Occurs once the user right clicks the control.

event **AnchorClick** (AnchorID as String, Options as String)

Occurs when an anchor element is clicked.

Type	Description
AnchorID as String	A string expression that indicates the identifier of the anchor
Options as String	A string expression that specifies options of the anchor element.

The control fires the AnchorClick event to notify that the user clicks an anchor element. An anchor is a piece of text or some other object (for example an image) which marks the beginning and/or the end of a hypertext link. The **<a>** element is used to mark that piece of text (or inline image), and to give its hypertextual relationship to other documents. The AnchorClick event is fired only if prior clicking the control it shows the hand cursor. For instance, if the cell is disabled, the hand cursor is not shown when hovers the anchor element, and so the AnchorClick event is not fired. Use the [FormatAnchor](#) property to specify the visual effect for anchor elements. For instance, if the user clicks the anchor **<a1>anchor**, the control fires the AnchorClick event, where the AnchorID parameter is 1, and the Options parameter is empty. Also, if the user clicks the anchor **<a1;youreextradata>anchor**, the AnchorID parameter of the AnchorClick event is 1, and the Options parameter is "youreextradata". Use the [AnchorFromPoint](#) property to retrieve the identifier of the anchor element from the cursor.

Syntax for AnchorClick event, **/NET** version, on:

```
C# private void AnchorClick(object sender,string  AnchorID,string  Options)
{
}
```

```
VB Private Sub AnchorClick(ByVal sender As System.Object,ByVal AnchorID As
String,ByVal Options As String) Handles AnchorClick
End Sub
```

Syntax for AnchorClick event, **/COM** version, on:

```
C# private void AnchorClick(object sender,
AxEXGAUGELib._IGaugeEvents_AnchorClickEvent e)
{
}
```

event Change (Layer as Long)

Occurs when the layer's value is changed.

Type	Description
Layer as Long	A long expression that specifies the index of the layer whose value is being changed. The Item property of Layers collection gets the layer based on its index.

The Change event occurs when any of the following properties:

- [Value](#), specifies the layer's value.
- [OffsetX](#), specifies a value that indicates x-offset of the layer.
- [OffsetY](#), indicates a value that indicates y-offset of the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.

are changed. For instance, you can use the Change event to update other layers when one of the layer is changed. The [OnDrag](#) property indicates the action to be performed when the user drags the layer. The [DragStart](#) / [Drag](#) / [DragEnd](#) events notify your application when a layer is dragged. The [MouseWheel](#) occurs when the mouse wheel is rolled.

Syntax for Change event, **/NET** version, on:

```
C# private void Change(object sender,int Layer)
{
}
```

```
VB Private Sub Change(ByVal sender As System.Object,ByVal Layer As Integer)

event Click ()

Occurs when the user presses and then releases the left mouse button over the control.

Type

Description

The Click event is fired when the user releases the left mouse button over the control. Use a [MouseDown](#) or [MouseUp](#) event procedure to specify actions that will occur when a mouse button is pressed or released. Unlike the Click and [DbClick](#) events, MouseDown and MouseUp events lets you distinguish between the left, right, and middle mouse buttons. You can also write code for mouse-keyboard combinations that use the SHIFT, CTRL, and ALT keyboard modifiers. You can use the [LayerFromPoint\(-1,-1\)](#) property to get the layer from the cursor. The Click event is not fired if you click, drag and release the mouse over the control. The [OnDrag](#) property indicates the action to be performed when the user clicks and drags the layer.

Syntax for Click event, **/NET** version, on:

```
C# private void Click(object sender)
{
}
```

```
VB Private Sub Click(ByVal sender As System.Object) Handles Click
End Sub
```

event DbtClick (Shift as Integer, X as OLE_XPOS_PIXELS, Y as OLE_YPOS_PIXELS)

Occurs when the user dbtclk the left mouse button over an object.

Type	Description
Shift as Integer	An integer that corresponds to the state of the SHIFT, CTRL, and ALT keys.
X as OLE_XPOS_PIXELS	A single that specifies the current X location of the mouse pointer. The x values is always expressed in container coordinates.
Y as OLE_YPOS_PIXELS	A single that specifies the current Y location of the mouse pointer. The y values is always expressed in container coordinates

The DbtClick event is fired when user double clicks the control. You can use the [LayerFromPoint\(-1,-1\)](#) property to get the layer from the cursor. The Click event is not fired if you click, drag and release the mouse over the control. The [OnDrag](#) property indicates the action to be performed when the user clicks and drags the layer.

event Drag (DragInfo as DragInfo)

Notifies that the user drags the layer.

Type	Description
DragInfo as DragInfo	A DragInfo object that carries information about the dragging operation.

Any layer on the control supports drag operations like moving, rotation, or combination of them, when the user clicks and drags a layer. The drag operation automatically starts when the user clicks a visible, selectable and draggable layer. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (draggable). The [Visible](#) property shows or hides a specific layer (visible). The [Selectable](#) property returns or sets a value that indicates whether the layer is selectable. The [Change](#) event occurs when the layer's value is changed.

The control fires the drag events in the following order:

- [DragStart](#) event notifies that a layer begins to drag. You can use the DragStart event to cancel the dragging operation.
- Drag event notifies that the layer is dragging. You can use the Drag event to perform other actions, on any layer during the dragging operation.
- [DragEnd](#) event notifies that the dragging the layer ends. You can use the DragEnd event to perform other actions, on any layer when dragging operation ends.

Syntax for Drag event, **/NET** version, on:

```
C# private void Drag(object sender,exontrol.EXGAUGELib.DragInfo  DragInfo)
{
}
```

```
VB Private Sub Drag(ByVal sender As System.Object,ByVal DragInfo As

event DragEnd (DragInfo as DragInfo, Cancel as Boolean)

Occurs once the user ends dragging a layer.

Type	Description
DragInfo as DragInfo	A DragInfo object that carries information about the dragging operation.
Cancel as Boolean	A Boolean expression that specifies whether the dragging operation was canceled, for instance, the user presses the ESC during dragging operation.

Any layer on the control supports drag operations like moving, rotation, or combination of them, when the user clicks and drags a layer. The drag operation automatically starts when the user clicks a visible, selectable and draggable layer. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (draggable). The [Visible](#) property shows or hides a specific layer (visible). The [Selectable](#) property returns or sets a value that indicates whether the layer is selectable. The [Change](#) event occurs when the layer's value is changed.

The control fires the drag events in the following order:

- [DragStart](#) event notifies that a layer begins to drag. You can use the DragStart event to cancel the dragging operation.
- [Drag](#) event notifies that the layer is dragging. You can use the Drag event to perform other actions, on any layer during the dragging operation.
- DragEnd event notifies that the dragging the layer ends. You can use the DragEnd event to perform other actions, on any layer when dragging operation ends.

Syntax for DragEnd event, **/NET** version, on:

C#	<pre>private void DragEnd(object sender,exontrol.EXGAUGELib.DragInfo DragInfo,bool Cancel) { }</pre>
VB	<pre>Private Sub DragEnd(ByVal sender As System.Object,ByVal DragInfo As exontrol.EXGAUGELib.DragInfo,ByVal Cancel As Boolean) Handles DragEnd End Sub</pre>

event DragStart (DragInfo as DragInfo, Cancel as Boolean)

Occurs once the user starts dragging a layer.

Type	Description
DragInfo as DragInfo	A DragInfo object that carries information about the dragging operation. You can use UserData property of the DragInfo object to associate any-extra data to the current dragging operation.
Cancel as Boolean	A Boolean expression that specifies whether the dragging operation should be canceled, or can continue. By default, the Cancel parameter is False, so you can change the Cancel parameter during the DragStart event to prevent dragging any layer on the control.

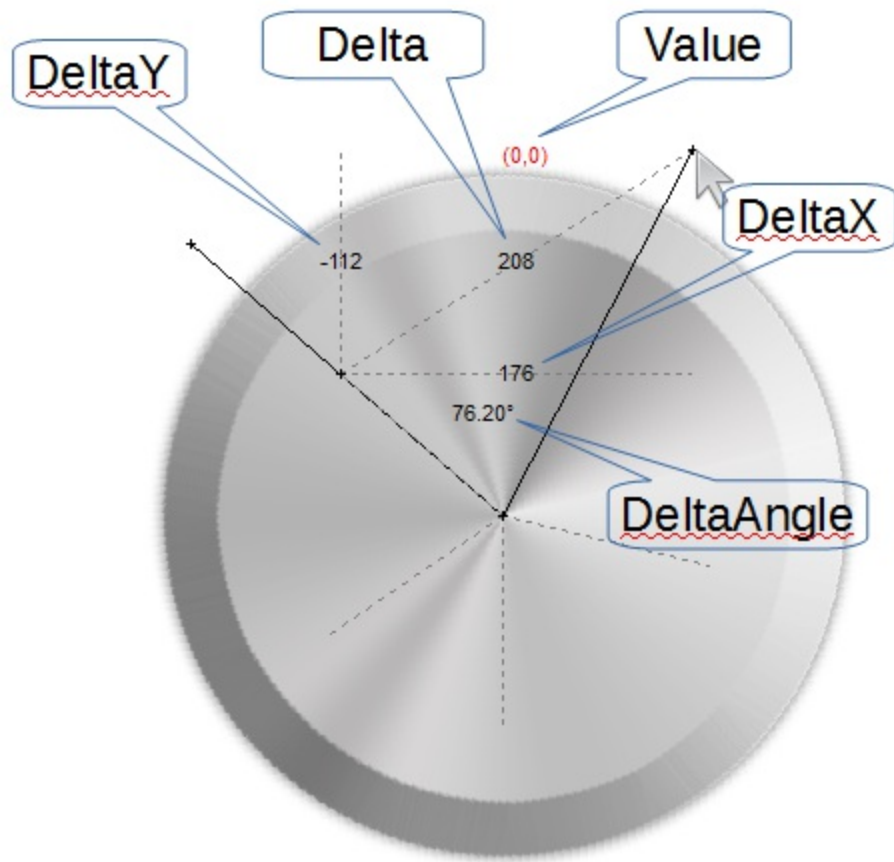

Any layer on the control supports drag operations like moving, rotation, or combination of them, when the user clicks and drags a layer. The drag operation automatically starts when the user clicks a visible, selectable and draggable layer. The [OnDrag](#) property indicates the action to be performed when the user drags the layer (draggable). The [Visible](#) property shows or hides a specific layer (visible). The [Selectable](#) property returns or sets a value that indicates whether the layer is selectable. The [Change](#) event occurs when the layer's value is changed.

The control fires the drag events in the following order:

- DragStart event notifies that a layer begins to drag. You can use the DragStart event to cancel the dragging operation.
- [Drag](#) event notifies that the layer is dragging. You can use the Drag event to perform other actions, on any layer during the dragging operation.
- [DragEnd](#) event notifies that the dragging the layer ends. You can use the DragEnd event to perform other actions, on any layer when dragging operation ends.

You can use the [Debug](#) property of the DragInfo object to display debugging information during dragging.

The following screen show shows debugging information during dragging:

event Event (EventID as Long)

Notifies the application once the control fires an event.

Type	Description
EventID as Long	A Long expression that specifies the identifier of the event. Use the EventParam(-2) to display entire information about fired event (such as name, identifier, and properties).

The Event notification occurs ANY time the control fires an event.

This is useful for X++ language, which does not support event with parameters passed by reference.

In X++ the "Error executing code: FormActiveXControl (data source), method ... called with invalid parameters" occurs when handling events that have parameters passed by reference. Passed by reference, means that in the event handler, you can change the value for that parameter, and so the control will takes the new value, and use it. The X++ is NOT able to handle properly events with parameters by reference, so we have the solution.

The solution is using and handling the Event notification and EventParam method., instead handling the event that gives the "invalid parameters" error executing code.

Here's how the output is shown, when printing the EventParam(-2) during the Event event:

```
MouseIn/2( 0 )
MouseMove/-606( 0 , 0 , 184 , 420 )
MouseDown/-605( 1 , 0 , 184 , 420 )
DragStart/4( [Object] , =false )
MouseMove/-606( 1 , 0 , 185 , 420 )
Change/7( 0 )
Drag/5( [Object] )
DragEnd/6( [Object] , false )
MouseUp/-607( 1 , 0 , 337 , 382 )
MouseMove/-606( 0 , 0 , 338 , 383 )
MouseOut/3( 0 )
MouseMove/-606( 0 , 0 , 369 , 623 )
MouseMove/-606( 0 , 0 , 369 , 636 )
```

event KeyDown (KeyCode as Integer, Shift as Integer)

Occurs when the user presses a key while an object has the focus.

Type	Description
KeyCode as Integer	An integer that represent the key code.
Shift as Integer	An integer that corresponds to the state of the SHIFT, CTRL, and ALT keys at the time of the event. The shift argument is a bit field with the least-significant bits corresponding to the SHIFT key (bit 0), the CTRL key (bit 1), and the ALT key (bit 2). These bits correspond to the values 1, 2, and 4, respectively. Some, all, or none of the bits can be set, indicating that some, all, or none of the keys are pressed. For example, if both CTRL and ALT are pressed, the value of shift is 6.

Use KeyDown and [KeyUp](#) event procedures if you need to respond to both the pressing and releasing of a key. You test for a condition by first assigning each result to a temporary integer variable and then comparing shift to a bit mask. Use the And operator with the shift argument to test whether the condition is greater than 0, indicating that the modifier was pressed, as in this example:

```
ShiftDown = (Shift And 1) > 0
CtrlDown = (Shift And 2) > 0
AltDown = (Shift And 4) > 0
```

In a procedure, you can test for any combination of conditions, as in this example:
If AltDown And CtrlDown Then

Syntax for KeyDown event, **/NET** version, on:

event KeyPress (KeyAscii as Integer)

Occurs when the user presses and releases an ANSI key.

Type	Description
KeyAscii as Integer	An integer that returns a standard numeric ANSI keycode.

The KeyPress event lets you immediately test keystrokes for validity or for formatting characters as they are typed. Changing the value of the keyascii argument changes the character displayed. Use [KeyDown](#) and [KeyUp](#) event procedures to handle any keystroke not recognized by KeyPress, such as function keys, editing keys, navigation keys, and any combinations of these with keyboard modifiers. Unlike the KeyDown and KeyUp events, KeyPress does not indicate the physical state of the keyboard; instead, it passes a character. KeyPress interprets the uppercase and lowercase of each character as separate key codes and, therefore, as two separate characters.

Syntax for KeyPress event, **/NET** version, on:

```
C# private void KeyPress(object sender,ref short  KeyAscii)
{
}
```

```
VB Private Sub KeyPress(ByVal sender As System.Object,ByRef KeyAscii As Short)

event KeyUp (KeyCode as Integer, Shift as Integer)

Occurs when the user releases a key while an object has the focus.

Type	Description
KeyCode as Integer	An integer that represent the key code.
Shift as Integer	An integer that corresponds to the state of the SHIFT, CTRL, and ALT keys at the time of the event. The shift argument is a bit field with the least-significant bits corresponding to the SHIFT key (bit 0), the CTRL key (bit 1), and the ALT key (bit 2). These bits correspond to the values 1, 2, and 4, respectively. Some, all, or none of the bits can be set, indicating that some, all, or none of the keys are pressed. For example, if both CTRL and ALT are pressed, the value of shift is 6.

Use the KeyUp event procedure to respond to the releasing of a key.

Syntax for KeyUp event, **/NET** version, on:

event MouseDown (Button as Integer, Shift as Integer, X as OLE_XPOS_PIXELS, Y as OLE_YPOS_PIXELS)

Occurs when the user presses a mouse button.

Type	Description
Button as Integer	An integer that identifies the button that was pressed to cause the event
Shift as Integer	An integer that corresponds to the state of the SHIFT, CTRL, and ALT keys when the button specified in the button argument is pressed or released.
X as OLE_XPOS_PIXELS	A single that specifies the current X location of the mouse pointer. The X value is always expressed in container coordinates.
Y as OLE_YPOS_PIXELS	A single that specifies the current Y location of the mouse pointer. The Y value is always expressed in container coordinates.

Use a MouseDown or [MouseUp](#) event procedure to specify actions that will occur when a mouse button is pressed or released. Unlike the [Click](#) and [DbClick](#) events, MouseDown and MouseUp events lets you distinguish between the left, right, and middle mouse buttons. You can also write code for mouse-keyboard combinations that use the SHIFT, CTRL, and ALT keyboard modifiers. You can use the [LayerFromPoint\(-1,-1\)](#) property to get the layer from the cursor. The Click event is not fired if you click, drag and release the mouse over the control. The [OnDrag](#) property indicates the action to be performed when the user clicks and drags the layer.

Syntax for MouseDown event, **/NET** version, on:

C#

```
private void MouseDownEvent(object sender,short  Button,short  Shift,int  X,int Y)
{
}
```

VB

```

event MouseIn (Layer as Long)

Notifies that the cursor enters the layer.

Type	Description
Layer as Long	A long expression that specifies the index of the layer where the cursor is entering. The Item property of Layers collection gets the layer based on its index.

The MouseIn / [MouseOut](#) event notifies your application when the cursor is entering / leaving the layer. The [MouseMove](#) event is generated continually as the mouse pointer moves across objects. The [AllowSmoothChange](#) property specifies the properties of the layers that support smooth change. For instance, you can use the MouseIn / MouseOut event to change gradually the brightness / contrast or the transparency, of the layer, while the [AllowSmoothChange](#) property is not exSmoothChangeless.

Syntax for MouseIn event, **/NET** version, on:

C#

```
private void MouseIn(object sender,int  Layer)
{
}
```

VB

```

The following samples shows how you can change the layer's brightness when the cursor enters / leaves the layer:

VBA (MS Access, Excell...)

' MouseIn event - Notifies that the cursor enters the layer.

```
Private Sub Gauge1_MouseIn(ByVal Layer As Long)
    With Gauge1
        With .Layers.Item(Layer)
            .Brightness(1) = 100
            .Brightness(2) = 0
            .Brightness(3) = 0
        End With
    End With
End Sub
```

' MouseOut event - Notifies that the cursor exits the layer.

```
Private Sub Gauge1_MouseOut(ByVal Layer As Long)
```

```

With Gauge1
    With .Layers.Item(Layer)
        .Brightness(1) = Gauge1.DefaultLayer(128)
        .Brightness(2) = Gauge1.DefaultLayer(128)
        .Brightness(3) = Gauge1.DefaultLayer(128)
    End With
End With
End Sub

With Gauge1
    .DefaultLayer(128) = 51
    .PicturesPath = "C:\Program Files
(x86)\Exontrol\ExGauge\Sample\Design\Circular\Knob"
    .PicturesName = "`Layer` + int(value + 1) + `.png`"
    .Layers.Count = 1
End With

```

VB6

```

' MouseIn event - Notifies that the cursor enters the layer.
Private Sub Gauge1_MouseIn(ByVal Layer As Long)
    With Gauge1
        With .Layers.Item(Layer)

```

event MouseEventArgs (Button as Integer, Shift as Integer, X as OLE_XPOS_PIXELS, Y as OLE_YPOS_PIXELS)

Occurs when the user moves the mouse.

Type	Description
Button as Integer	An integer that corresponds to the state of the mouse buttons in which a bit is set if the button is down. Gets which mouse button was pressed as 1 for Left Mouse Button, 2 for Right Mouse Button and 4 for Middle Mouse Button.
Shift as Integer	An integer that corresponds to the state of the SHIFT, CTRL, and ALT keys.
X as OLE_XPOS_PIXELS	A single that specifies the current X location of the mouse pointer. The x values is always expressed in container coordinates.
Y as OLE_YPOS_PIXELS	A single that specifies the current Y location of the mouse pointer. The y values is always expressed in container coordinates.

The MouseEventArgs event is generated continually as the mouse pointer moves across objects. Unless another object has captured the mouse, an object recognizes a MouseEventArgs event whenever the mouse position is within its borders. You can use the [LayerFromPoint\(-1,-1\)](#) property to get the layer from the cursor. The Click event is not fired if you click, drag and release the mouse over the control. The [OnDrag](#) property indicates the action to be performed when the user clicks and drags the layer. The [MouseIn](#) / [MouseOut](#) event notifies your application when the cursor is entering / leaving the layer.

Syntax for MouseEventArgs event, **/NET** version, on:

```
C# private void MouseEventArgsEvent(object sender,short Button,short Shift,int X,int Y)
{
}
```

```
VB Private Sub MouseEventArgsEvent(ByVal sender As System.Object,ByVal Button As Short,ByVal Shift As Short,ByVal X As Integer,ByVal Y As Integer) Handles MouseEventArgs

event MouseOut (Layer as Long)

Notifies that the cursor exits the layer.

Type	Description
Layer as Long	A long expression that specifies the index of the layer where the cursor is leaving. The Item property of Layers collection gets the layer based on its index.

The [MouseIn](#) / MouseOut event notifies your application when the cursor is entering / leaving the layer. The [MouseMove](#) event is generated continually as the mouse pointer moves across objects. The [AllowSmoothChange](#) property specifies the properties of the layers that support smooth change. For instance, you can use the MouseIn / MouseOut event to change gradually the brightness / contrast or the transparency, of the layer, while the [AllowSmoothChange](#) property is not exSmoothChangeless.

Syntax for MouseOut event, **/NET** version, on:

C#private void MouseOut(object sender,int Layer){}

VBPrivate Sub MouseOut(ByVal sender As System.Object,ByVal Layer As Integer)Handles MouseOutEnd Sub

Syntax for MouseOut event, **/COM** version, on:

```

event MouseUp (Button as Integer, Shift as Integer, X as OLE_XPOS_PIXELS, Y as OLE_YPOS_PIXELS)

Occurs when the user releases a mouse button.

Type	Description
Button as Integer	An integer that identifies the button that was pressed to cause the event.
Shift as Integer	An integer that corresponds to the state of the SHIFT, CTRL, and ALT keys when the button specified in the button argument is pressed or released.
X as OLE_XPOS_PIXELS	A single that specifies the current X location of the mouse pointer. The x values is always expressed in container coordinates.
Y as OLE_YPOS_PIXELS	A single that specifies the current Y location of the mouse pointer. The y values is always expressed in container coordinates.

Use a [MouseDown](#) or MouseUp event procedure to specify actions that will occur when a mouse button is pressed or released. Unlike the [Click](#) and [DbClick](#) events, MouseDown and MouseUp events lets you distinguish between the left, right, and middle mouse buttons. You can also write code for mouse-keyboard combinations that use the SHIFT, CTRL, and ALT keyboard modifiers. You can use the [LayerFromPoint\(-1,-1\)](#) property to get the layer from the cursor. The Click event is not fired if you click, drag and release the mouse over the control. The [OnDrag](#) property indicates the action to be performed when the user clicks and drags the layer.

Syntax for MouseUp event, **/NET** version, on:

```
C# private void MouseUpEvent(object sender,short  Button,short  Shift,int  X,int  Y)
{
}
```

```

event MouseWheel (Delta as Long)

Occurs when the mouse wheel moves while the control has focus

Type	Description
Delta as Long	A long expression that specifies the direction and the quantity that the mouse wheel has been rolled. For instance, 1 indicates that the user rolls the mouse wheel up, -1 indicates that the user rolls the mouse wheel down. Any other value may indicate that the mouse wheel has been rolled quicker.

The MouseWheel occurs when the mouse wheel is rolled. You can use the MouseWheel event to perform different actions on any layer when the user rolls the mouse wheel. For instance, you can update the layer's value when the user rolls the muse wheel. You can use the [LayerFromPoint\(-1,-1\)](#) property to get the layer from the cursor. The [FormatABC](#) method formats the A,B,C values based on the giving expression and returns the result.

You can use any of the following properties to update the layer:

- [Value](#), specifies the layer's value.
- [OffsetX](#), specifies a value that indicates x-offset of the layer.
- [OffsetY](#), indicates a value that indicates y-offset of the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [Clip](#), to clip any layer

The [Change](#) event occurs when the layer's value is changed.

Syntax for MouseWheel event, **/NET** version, on:

event RClick ()

Occurs once the user right clicks the control.

Type	Description
------	-------------

Use the RClick event to add your context menu. The RClick event notifies your application when the user right clicks the control. Use the [Click](#) event to notify your application that the user clicks the control (using the left mouse button). Use the [MouseDown](#) or [MouseUp](#) event if you require the cursor position during the RClick event. The [MouseIn](#) / [MouseOut](#) event notifies your application when the cursor is entering / leaving the layer. You can use the [LayerFromPoint\(-1,-1\)](#) property to get the layer from the cursor. The Click event is not fired if you click, drag and release the mouse over the control. The [OnDrag](#) property indicates the action to be performed when the user clicks and drags the layer.

Syntax for RClick event, **/NET** version, on:

C#	<pre>private void RClick(object sender) { }</pre>
VB	<pre>Private Sub RClick(ByVal sender As System.Object) Handles RClick End Sub</pre>

event Timer (TickCount as Long)

Occurs when the interval elapses.

Type	Description
TickCount as Long	A Long expression that specifies the number of milliseconds that have elapsed since the system was started, up to 49.7 days.

The Timer event occurs when the timer interval elapses. The [TimerInterval](#) property returns or sets the number of milliseconds between calls of control's Timer event. You can use the Timer event to perform different actions on any layer when a specified time elapsed. For instance, you can rotate the layer every second, or any dial of a clock, and so on.

The [FormatABC](#) method formats the A,B,C values based on the giving expression and returns the result.

You can use any of the following properties to update the layer:

- [Value](#), specifies the layer's value.
- [OffsetX](#), specifies a value that indicates x-offset of the layer.
- [OffsetY](#), indicates a value that indicates y-offset of the layer.
- [RotateAngle](#), specifies the angle to rotate the layer.
- [Clip](#), to clip any layer

The [Change](#) event occurs when the layer's value is changed.

Syntax for Timer event, **/NET** version, on:

C#private void Timer(object sender,int TickCount){}

VBPrivate Sub Timer(ByVal sender As System.Object,ByVal TickCount As Integer)Handles TimerEnd Sub

property Gauge.TemplateDef as Variant

Defines inside variables for the next Template/ExecuteTemplate call.

Type	Description
Variant	A string expression that indicates the Dim declaration, or any Object expression to be assigned to previously declared variables.

The TemplateDef property has been added to allow programming languages such as dBASE Plus to set control's properties with multiple parameters. It is known that programming languages such as **dBASE Plus** or **XBasic from AlphaFive**, does not support setting a property with multiple parameters. In other words, these programming languages does not support something like *Property(Parameters) = Value*, so our controls provide an alternative using the TemplateDef method. The first call of the TemplateDef should be a declaration such as "Dim a,b" which means the next 2 calls of the TemplateDef defines the variables a and b. The next call should be [Template](#) or [ExecuteTemplate](#) property which can use the variable a and b being defined previously.

So, calling the TemplateDef property should be as follows:

```
with (Control)
  TemplateDef = [Dim var_Column]
  TemplateDef = var_Column
  Template = [var_Column.Def(4) = 255]
endwith
```

This sample allocates a variable var_Column, assigns the value to the variable (the second call of the TemplateDef), and the Template call uses the var_Column variable (as an object), to call its Def property with the parameter 4.

Let's say we need to define the background color for a specified column, so we need to call the Def(exCellBackColor) property of the column, to define the color for all cells in the column.

The following **VB6** sample shows setting the Def property such as:

```
With Control
  .Columns.Add("Column 1").Def(exCellBackColor) = 255
  .Columns.Add "Column 2"
  .Items.AddItem 0
  .Items.AddItem 1
```

```
.Items.AddItem 2  
End With
```

In **dBASE Plus**, calling the Def(4) has no effect, instead using the TemplateDef helps you to use properly the Def property as follows:

```
local Control,var_Column  
  
Control = form.Active1.nativeObject  
// Control.Columns.Add("Column 1").Def(4) = 255  
var_Column = Control.Columns.Add("Column 1")  
with (Control)  
    TemplateDef = [Dim var_Column]  
    TemplateDef = var_Column  
    Template = [var_Column.Def(4) = 255]  
endwith  
Control.Columns.Add("Column 2")  
Control.Items.AddItem(0)  
Control.Items.AddItem(1)  
Control.Items.AddItem(2)
```

The equivalent sample for **XBasic in A5**, is as follows:

```
Dim Control as P  
Dim var_Column as P  
  
Control = topparent:CONTROL_ACTIVEX1.activex  
' Control.Columns.Add("Column 1").Def(4) = 255  
var_Column = Control.Columns.Add("Column 1")  
Control.TemplateDef = "Dim var_Column"  
Control.TemplateDef = var_Column  
Control.Template = "var_Column.Def(4) = 255"  
  
Control.Columns.Add("Column 2")  
Control.Items.AddItem(0)  
Control.Items.AddItem(1)  
Control.Items.AddItem(2)
```

The samples just call the `Column.Def(4) = Value`, using the `TemplateDef`. The first call of `TemplateDef` property is `"Dim var_Column"`, which indicates that the next call of the `TemplateDef` will defines the value of the variable `var_Column`, in other words, it defines the object `var_Column`. The last call of the `Template` property uses the `var_Column` member to use the x-script and so to set the `Def` property so a new color is being assigned to the column.

The `TemplateDef`, [Template](#) and [ExecuteTemplate](#) support x-script language (`Template` script of the `Exontrols`), like explained bellow:

The `Template` or x-script is composed by lines of instructions. Instructions are separated by `"\n\r"` (newline characters) or `";"` character. The `;` character may be available only for newer versions of the components.

An x-script instruction/line can be one of the following:

- **Dim** list of variables *Declares the variables. Multiple variables are separated by commas.* (Sample: `Dim h, h1, h2`)
- `variable = property(list of arguments)` *Assigns the result of the property to a variable. The "variable" is the name of a declared variable. The "property" is the property name of the object in the context. The "list or arguments" may include variables or values separated by commas.* (Sample: `h = InsertItem(0,"New Child")`)
- `property(list of arguments) = value` *Changes the property. The value can be a variable, a string, a number, a boolean value or a RGB value.*
- `method(list of arguments)` *Invokes the method. The "list or arguments" may include variables or values separated by commas.*
- `{` *Beginning the object's context. The properties or methods called between `{` and `}` are related to the last object returned by the property prior to `{` declaration.*
- `}` *Ending the object's context*
- `object.property(list of arguments).property(list of arguments)....` *The `.` (dot) character splits the object from its property. For instance, the `Columns.Add("Column1").HeaderBackColor = RGB(255,0,0)`, adds a new column and changes the column's header back color.*

The x-script may uses constant expressions as follow:

- *boolean* expression with possible values as *True* or *False*
- *numeric* expression may starts with `0x` which indicates a hexa decimal representation, else it should starts with digit, or `+/-` followed by a digit, and `.` is the decimal separator. Sample: `13` indicates the integer `13`, or `12.45` indicates the double expression `12,45`
- *date* expression is delimited by `#` character in the format `#mm/dd/yyyy hh:mm:ss#`. Sample: `#31/12/1971#` indicates the December 31, 1971
- *string* expression is delimited by `"` or ``` characters. If using the ``` character, please

make sure that it is different than ' which allows adding comments inline. *Sample: "text" indicates the string text.*

Also , the template or x-script code may support general functions as follows:

- **Me** *property indicates the original object.*
- **RGB(R,G,B)** *property retrieves an RGB value, where the R, G, B are byte values that indicates the R G B values for the color being specified. For instance, the following code changes the control's background color to red: BackColor = RGB(255,0,0)*
- **LoadPicture(file)** *property loads a picture from a file or from BASE64 encoded strings, and returns a Picture object required by the picture properties.*
- **CreateObject(progID)** *property creates and retrieves a single uninitialized object of the class associated with a specified program identifier.*

property Gauge.Template as String

Specifies the control's template.

Type	Description
String	A string expression that defines the control's template

The control's template uses the X-Script language to initialize the control's content. Use the Template property page of the control to update the control's Template property. Use the Template property to execute code by passing instructions as a string (template string). Use the [ToTemplate](#) property to generate the control's content to template format. Use the [ExecuteTemplate](#) property to get the result of executing a template script.

The Exontrol's [eXHelper](#) tool helps you to find easy and quickly the answers and the source code for your questions regarding the usage of our UI components.

Most of our UI components provide a Template page that's accessible in design mode. No matter what programming language you are using, you can have a quick view of the component's features using the WYSWYG Template editor.

- Place the control to your form or dialog.
- Locate the Properties item, in the control's context menu, in design mode. If your environment doesn't provide a Properties item in the control's context menu, please try to locate in the Properties browser.
- Click it, and locate the Template page.
- Click the Help button. In the left side, you will see the component, in the right side, you will see a x-script code that calls methods and properties of the control.

The control's Template page helps user to initialize the control's look and feel in design mode, using the x-script language that's easy and powerful. The Template page displays the control on the left side of the page. On the right side of the Template page, a simple editor is displayed where user writes the initialization code. The control's look and feel is automatically updated as soon as the user types new instructions. The Template script is saved to the container persistence (when Apply button is pressed), and it is executed when the control is initialized at runtime. Any component that provides a WYSWYG Template page, provides a Template property. The Template property executes code from a string (template string).

The Template or x-script is composed by lines of instructions. Instructions are separated by "\n\r" (newline characters) or ";" character. The ; character may be available only for newer versions of the components.

An x-script instruction/line can be one of the following:

- **Dim** list of variables *Declares the variables. Multiple variables are separated by commas. (Sample: Dim h, h1, h2)*
- **variable = property(list of arguments)** *Assigns the result of the property to a variable. The "variable" is the name of a declared variable. The "property" is the property name of the object in the context. The "list or arguments" may include variables or values separated by commas. (Sample: h = InsertItem(0,"New Child"))*
- **property(list of arguments) = value** *Changes the property. The value can be a variable, a string, a number, a boolean value or a RGB value.*
- **method(list of arguments)** *Invokes the method. The "list or arguments" may include variables or values separated by commas.*
- **{** *Beginning the object's context. The properties or methods called between { and } are related to the last object returned by the property prior to { declaration.*
- **}** *Ending the object's context*
- **object.property(list of arguments).property(list of arguments)....** *The .(dot) character splits the object from its property. For instance, the Columns.Add("Column1").HeaderBackColor = RGB(255,0,0), adds a new column and changes the column's header back color.*

The x-script may uses constant expressions as follow:

- *boolean* expression with possible values as *True* or *False*
- *numeric* expression may starts with 0x which indicates a hexa decimal representation, else it should starts with digit, or +/- followed by a digit, and . is the decimal separator. *Sample: 13 indicates the integer 13, or 12.45 indicates the double expression 12,45*
- *date* expression is delimited by # character in the format #mm/dd/yyyy hh:mm:ss#. *Sample: #31/12/1971# indicates the December 31, 1971*
- *string* expression is delimited by " or ` characters. If using the ` character, please make sure that it is different than ' which allows adding comments inline. *Sample: "text" indicates the string text.*

Also , the template or x-script code may support general functions as follows:

- **Me** *property indicates the original object.*
- **RGB(R,G,B)** *property retrieves an RGB value, where the R, G, B are byte values that indicates the R G B values for the color being specified. For instance, the following code changes the control's background color to red: BackColor = RGB(255,0,0)*
- **LoadPicture(file)** *property loads a picture from a file or from BASE64 encoded strings, and returns a Picture object required by the picture properties.*
- **CreateObject(progID)** *property creates and retrieves a single uninitialized object of the class associated with a specified program identifier.*

For instance, the following script:

```
PicturesPath = "C:\Program Files\Exontrol\ExGauge\Sample\Design\Circular\Knob"
```

```
PicturesName = "`Layer` + str(value + 1) + `.png`"
```

```
Layers.Count = 10
```

generates:

method Gauge.ExecuteTemplate (Template as String)

Executes a template and returns the result.

Type	Description
Template as String	A Template string being executed
Return	Description
Variant	A Variant expression that indicates the result after executing the Template.

Use the ExecuteTemplate property to returns the result of executing a template file. Use the [Template](#) property to execute a template without returning any result. Use the ExecuteTemplate property to execute code by passing instructions as a string (template string).

For instance, the following sample retrieves the control's background color:

```
Debug.Print Gauge1.ExecuteTemplate("BackColor")
```

Most of our UI components provide a Template page that's accessible in design mode. No matter what programming language you are using, you can have a quick view of the component's features using the WYSWYG Template editor.

- Place the control to your form or dialog.
- Locate the Properties item, in the control's context menu, in design mode. If your environment doesn't provide a Properties item in the control's context menu, please try to locate in the Properties browser.
- Click it, and locate the Template page.
- Click the Help button. In the left side, you will see the component, in the right side, you will see a x-script code that calls methods and properties of the control.

The control's Template page helps user to initialize the control's look and feel in design mode, using the x-script language that's easy and powerful. The Template page displays the control on the left side of the page. On the right side of the Template page, a simple editor is displayed where user writes the initialization code. The control's look and feel is automatically updated as soon as the user types new instructions. - method(list of arguments) *Invokes the method. The "list or arguments" may include variables or values separated by commas.*
- { *Beginning the object's context. The properties or methods called between { and } are related to the last object returned by the property prior to { declaration.*
- } *Ending the object's context*
- object. property(list of arguments).property(list of arguments).... *The .(dot) character splits the object from its property. For instance, the Columns.Add("Column1").HeaderBackColor = RGB(255,0,0), adds a new column and changes the column's header back color.*

The x-script may uses constant expressions as follow:

- *boolean* expression with possible values as *True* or *False*
- *numeric* expression may starts with 0x which indicates a hexa decimal representation, else it should starts with digit, or +/- followed by a digit, and . is the decimal separator. *Sample: 13 indicates the integer 13, or 12.45 indicates the double expression 12,45*
- *date* expression is delimited by # character in the format #mm/dd/yyyy hh:mm:ss#. *Sample: #31/12/1971# indicates the December 31, 1971*
- *string* expression is delimited by " or ` characters. If using the ` character, please make sure that it is different than ' which allows adding comments inline. *Sample: "text" indicates the string text.*

Also , the template or x-script code may support general functions as follows:

- **Me** *property indicates the original object.*
- **RGB(R,G,B)** *property retrieves an RGB value, where the R, G, B are byte values that indicates the R G B values for the color being specified. For instance, the following code changes the control's background color to red: BackColor = RGB(255,0,0)*
- **LoadPicture(file)** *property loads a picture from a file or from BASE64 encoded strings, and returns a Picture object required by the picture properties.*
- **CreateObject(progID)** *property creates and retrieves a single uninitialized object of*

the class associated with a specified program identifier.
